(54) Title: METHODS FOR MULTIPLE PARAMETER SCREENING AND EVOLUTION OF CELLS TO PRODUCE SMALL MOLECULES WITH MULTIPLE FUNCTIONALITIES

Example of droplet selected:
No activation of RXR-RXR
and activation of RXR-PPAR γ

(57) Abstract: The present invention relates to the field of selecting cells producing compounds that fulfil at least 2 predetermined functionalities. The invention primarily focuses on methods for screening of cells for two or more functionalities related to small molecules generated by host cells with novel gene assemblies. The methods in one aspect of the invention are combined with methods for evolution of cells to acquire at least two predetermined functionalities related to small molecules. Furthermore, the invention relates to methods for generation of lead compounds that are selected for a primary function and at least one further secondary function. The methods according to the invention may in particular be used in high throughput screening.

Methods for multiple parameter screening and evolution of cells to produce small molecules with multiple functionalities

This application is a continuation in part of PCT/DK02/00057 filed 25 January 2002, and claims priority from Danish patent application no. PA 2002 01174 filed 1 August 2002, both of which are hereby incorporated by reference in their entirety.

All patent and non-patent references cited in the application, or in the present application, are also hereby incorporated by reference in their entirety.

Field of invention

The present invention relates to the field of selecting cells producing compounds that fulfil at least 2 predetermined functionalities. The invention primarily focuses on methods for screening of cells for two or more functionalities related to small molecules generated by host cells with novel gene assemblies. The methods in one aspect of the invention are combined with methods for evolution of cells to acquire at least two predetermined functionalities related to small molecules. Furthermore, the invention relates to methods for generation of lead compounds that are selected for a primary function and at least one further secondary function. The methods according to the invention may in particular be used in high throughput screening.

Background of invention

Screening and selection

Methods for screening of cells for a given functionality using automated screening methods are known from the prior art. Examples of such methods include:

US 20010041333 A1 (Short & Keller) discloses among other thing a method for screening a polynucleotide library transformed into a suitable organism in a FACS (Fluorescence activated cell sorter). The library may be screened to determine whether the mixture has one or more specified activities. Another possibility is to screen scvf (single-chain fragment variable) libraries against multiple binding targets

(multiple epitope species, multiple receptor species) to obtain a multiplicity of scfv which have different binding specificities.

5 US 6,174,673 (Diversa) discloses the use of co-encapsulation of a library and an assay together with FACS. It is speculated that one could employ mixtures of substrates to simultaneously detect multiple enzyme activities of interest simultaneously or sequentially. FACS instruments can detect molecules that fluoresce at different wavelengths, hence substrates, which fluoresce at different wavelengths and indicate different enzyme activities can be employed.

10

WO 98/58085 (Diversa) discloses screening methods very similar to those of US 6,174,673. According to the description clones can be expressed to yield backbone structures, which can then be decorated in metabolically rich hosts, and finally screened for an activity of interest. Alternatively, clones can be expressed to yield
15 small molecules directly, which can be screened for an activity of interest. Furthermore, multiple probes can be designed and utilised to allow "multiplex" screening and/or enrichment. "Multiplex" screening and/or enrichment means that one is screening and/or enriching for more than one desirable outcome in multiple parallel and simultaneous screens.

20

US 5,837,458 (Maxygen) relates to methods for recursive sequence recombination. Different ways of screening and selection are described, among these the use of gel microdrops and facs with a reporter cell incorporated into the geldrop.

25 WO 00/08212 (Cellay) relates to forming a population of gel microdroplets encapsulating a population of biological entities (such as cells, vira, chromosomes), whereby at least some microdrops each encapsulate a single entity, contacting the population of microdrops with a probe which hybridises to a complementary sequence in an entity in at least one microdrop, and isolating the at least one
30 microdrop.

WO 98/58085 (Diversa) relates to the use of FACS for screening expression libraries, which may be co-encapsulated with the "screen".

WO 01/32829 (Novo Nordisk) discloses a method for screening host cells from a DNA library. The host cells are put into "sample" and the secretion of product into the sample is detected using fluorescence. A further feature is the establishment of a "means for correlation" between the host cell secretion and the fluorescence. The means for correlation are a physical link such as a chemical bond between the sample and the fluorescent label. The advantage is that the connection between cell and secreted product is not lost.

As can be seen from the above, most of the prior art focuses on development of modified enzymes and on modified antibodies. Common for all the references is that they focus on screening the cells for one functionality at a time.

Other references focussed on the development of reporter systems mention the possibility of having different reporter systems wherein the signals can be distinguished.

US 6,020,192 (University of Florida) relates to humanised green fluorescent protein genes. It is mentioned that GFPs that produce different colours permit simultaneous use of multiple reporter genes. As an example it is stated that differently coloured GFPs can be used to identify multiple cell populations in a mixed cell culture. Other options include tracking and determining the location of multiple proteins within a single cell, tissue or organism; differential promoter analysis in which gene expression from two different promoters is determined in the same cell, tissue or organism; and FACS sorting of mixed cell populations. The concept of using distinguishable reporter genes for the simultaneous screening for different traits harboured in the same cell is not disclosed.

Metcalf et al 1993 (Gene 129:17-25) discloses E. coli multiple deletional mutants that allow the simultaneous use of multiple reporter genes and Wood et al 1989, (Science 244:700-702) discloses several luciferase genes which produce luciferase which cause different colours when bioluminescent. It is stated that these could be useful in experiments in which multiple reporter genes are needed.

These multiple reporter systems may be useful for screening for the presence of more than one enzyme in a cell, but they do not focus on screening for properties related to small molecules produced by the host cells.

5 WO 98/41869 (Chromaxome) discloses an approach to drug screening that is designed to couple a screening assay both temporally and spatially to natural product synthesis in a microorganism. The reference provides a screening unit which is a gel droplet comprising a producing species that produces natural products for the drug screen, and an assay system that detects or measures a
10 desired biological activity. A producing species is coencapsulated with an assay system in a screening unit when the producing species is at a phase in its life cycle that is optimal for producing natural products, such as secondary metabolites. The producing species is spatially positioned relative to the assay system in the same unit such that compounds produced by the producing species can come into contact
15 with the assay system. If a compound possesses the desired activity, the assay system will generate a signal that enables the identification and/or isolation of the screening unit. The reference does not address other functionalities of the compounds than pharmacological ones. Thus in order to optimise a pharmaceutical compound many rounds of successive screens will have to be carried out and most
20 of the compounds found in the first rounds will not meet all the criteria as seen in standard drug discovery. Furthermore, the system is dependent on the cell cycle, since there is no control over gene expression in the producing species.

25 US 20010047029 (Handelsman et al) discloses triaryl cationic compounds that exhibit broad spectrum antibiotic and antifungal activity, pharmaceutical compositions containing the compounds, and methods of treating bacterial and fungal infections using the compounds. The compounds were initially isolated by screening a 25,000-member bacterial artificial chromosome (BAC) library of environmental (eDNA) from soil. At least one clone produced a dark brown melanin-
30 like compound that was found to have antibiotic activity. The compounds were isolated and synthesized de novo. From within the positive clone, a single open reading frame that shares extensive sequence similarity with members of the 4-hydroxyphenylpyruvate family of enzymes was found to be necessary and sufficient to confer the production of at least one of the subject compounds on *E. coli*.

WO 89/10566 (MASSACHUSETTS INSTITUTE OF TECHNOLOGY) discloses a process for capturing molecules at binding sites within gel microdroplets. The process also allows measurement or isolation of cells based on the captured molecules. The process involves creation of gel microdroplets (gel microdroplets) with binding sites for molecules secreted or released from cells. Gel microdroplets can optionally be incubated, and then measured for the presence of molecules captured at the gel microdroplet binding sites. The process allows measurement, and isolation of cells based on measurement, or allows isolation without measurement. This invention also comprises gel microdroplets containing marker entities which enhance the measurement of gel microdroplets, as are processes for forming and using such gel microdroplets.

WO 00/17643 (Cellomics Inc) and WO 98/38490 (Biodx Inc) disclose systems, methods and screens for monitoring the physiological response of cells to the addition of biologically active compounds. Methods of combining high throughput with high content spatial information at the cellular and subcellular level as well as temporal information about changes in physiological, biochemical and molecular activities are disclosed. These methods allow multiple types of cellular reactions to be studied simultaneously. The system is therefore suitable for further characterisation of lead compounds or for monitoring environmental samples for the presence of bio-active substances. However, these methods depend on fixation of the cells and are thus destructive and do not allow the recovery of live cells, therefore making the system useless for screening with the purpose of recovering the cells that produce the desired compounds. Furthermore the systems are based on multiwell formats of 96 or 386 wells and are thus not suited for the extremely high throughput needed when screening very large populations (10^6 - 10^{12}). The systems are also only able to give information on multiple aspects of known compounds. They do not provide any means for optimising small molecules with respect to multiple parameters.

30

Drug development

Drug development begins with the identification of a lead compound, based on the ability of the compound to exhibit a desired biological effect, such as the ability to inhibit bacterial growth, inhibit the activity of a target enzyme, increase or modulate

35

the uptake of neurotransmitters, and the like. Biological activity is typically determined on the basis of in vitro experimentation or assays designed to rapidly identify candidate drugs. Typically, the selection criteria have be very harsh to select only a small percentage of the compounds tested, since further development is low throughput and very expensive as it depends on medicinal chemists optimising very few (1-5) compounds per week.

Once a candidate or lead compound has been identified and selected for further development, its ADME/PK characteristics are determined. ADME/PK concerns the absorption, distribution, metabolism, excretion and pharmacokinetics of drugs in the body. The ADME/PK properties of a drug are critical, and often serve to distinguish pharmaceutical products from mere lead compounds. For example, a drug that is poorly absorbed orally may require intravenous (or other parenteral) administration to be effective, which may be unacceptable for the condition to be treated. A compound effective as an antibiotic may be ineffective to treat bacterial meningitis if its distribution does not carry it to the central nervous system. A compound that is rapidly metabolised and/or excreted may not reside in the body long enough to serve its intended purpose.

Thus, for a compound to be useable as a drug it must fulfil multiple functional requirements. It must interact with the target(s) and affect the function of the target in the desired manner. At the same time it should not interact with many other (often similar) targets or have major non-specific effects. And then it must further have the right physical-chemical parameters and be metabolised by the body in an acceptable manner.

Because of this intrinsic difficulty and complexity, the process of discovering and developing drugs has a very poor success rate and is thus extremely expensive (\$600mn per successful compound) and very time consuming (c. 8-12 years from discovery to clinic). Only c. 1 in 15 primary screens produce a compound that makes it into pre-clinical development and only 1 in 10 of these compounds then make it to market. The average pharmaceutical company spends 250 man-years of research and development effort for every compound that enters the clinic. Most pharmaceutical companies are, in consequence, failing to launch new drugs at the rate they require to satisfy their investors.

There is thus a need in the art to develop methods for producing lead compounds. By definition, optimised compounds have to fulfil multiple requirements. Thus, the current invention addresses one of the major bottlenecks in drug development.

5

Summary of invention

It is an aim of the present invention to screen cells or compositions of cells for two or more desired properties or functionalities. The principle behind the screening of cells according to the invention is to produce a great diversity of genes in each cell and a great diversity of genes among cells in a composition of cells, subject the composition to screening, and optionally evolution. The genes may be exchanged among the cells to evolve cells producing one or more compounds with the two or more desired properties or functionalities.

15

In a first aspect the invention relates to a method for screening a cell producing at least one compound, said screening being for two or more functionalities of said compound, said method comprising the steps of

20 a) providing a composition of cells, said composition of cells comprising cells each with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition contain different heterologous expressible nucleotide sequences, said cells being denoted producer cells,

25

b) performing one screening of said population of cells for at least 2 parameters related to the functionalities, and determining a selection criterion for each parameter,

30

c) selecting cells meeting at least one predetermined selection criterion.

The invention provides a method for generation of novel gene combinations through insertion of multiple heterologous genes into host cells with screening of these cells for two or more functionalities caused by small molecules synthesised by the host cells. By combining two or more functionalities in one screening round, the

35

screening process is speeded up and the likelihood of identifying compounds fulfilling all criteria is increased. The invention also permits the identification of cells capable of synthesising compounds that are not only active against e.g. a pharmacological target, but at the same time fulfil another criterion, e.g. related to ADMET parameters or pharmacokinetic parameters. The compounds synthesised by the cells identified by the methods of the present invention may thus have a higher degree of likelihood to make it into drugs, because they are not only identified for their activity against a pharmacological target. The cells as defined in step a) can be referred to as producer cells because they produce the compounds screened and selected for. This is to distinguish them from reporter cells which can be used in connection with the screening and selection.

According to one preferred embodiment, the promoters of the expression cassettes are controllable, so that gene expression can be controlled. In such a system, gene expression is not dependent on the cell cycle and the chance of discovering a novel compound are increased.

The design and assembly of expression cassettes contained within the artificial chromosomes as well as the many possible sources are described in detailed description part of the present invention. Other vectors apart from artificial chromosomes can be used for harbouring the heterologous expressible nucleotide sequences but preferably substantially all of these are placed on one or more artificial chromosomes inserted into the host cell, because artificial chromosomes can harbour large genetic inserts and replicate stably in the cells especially when selectable genetic markers are inserted into the artificial chromosomes.

The compound for which the screening and selection is performed can either be contained within the cell or be excreted from said cell. According to a preferred embodiment of the invention the compound selected for is a product of enzymatic activity, i.e. a non-native primary or a secondary metabolite synthesised or converted by at least one enzyme present in the selected cells. More preferably, a compound according to the invention is produced by the combined activities of at least 2 enzymes, at least one of those enzymes being encoded by a heterologous expressible nucleotide sequence, which is preferably located on an artificial chromosome. According to this embodiment the definition of a compound does not

encompass polynucleotides or translation products. On the other hand the invention may also result in the generation of novel proteins and enzymes through combination of different protein sub-units from different sources but these are not directly selected for.

5

One of the many applications of the present invention is the development of drugs or drug candidates. Therefore often at least one parameter is a parameter related to activity against a pharmacological target. This could be in the embodiment of screening for more than one aspect of the same pharmacological activity, e.g. screening for the activation/deactivation of a transcription factor and for the expression of one or more genes regulated by the transcription factor. In another embodiment it could be screening for a desired pharmacological activity and the absence of an undesired pharmacological activity. In another embodiment of this aspect, at least one parameter is a parameter related to activity against a pharmacological target, and at least one further parameter is an ADME parameter. The invention also provides screening methods which utilise any combination of the above parameters, e.g. in any order. By optimising compounds on multiple criteria, drug candidates can be identified that have an improved chance of getting through the costly clinical trials.

20

The parameters related to activity against a pharmacological target may be one or more of

- interaction or non-interaction with a ligand pharmacological target.
- interaction or absence of interaction with an enzyme pharmacological target.
- 25 • interaction or non-interaction with a receptor pharmacological target.
- inhibition or enhancement of expression of a gene or set of genes encoding a pharmacological target.
- the inhibition or enhancement of expression may be caused by the ability of a compound to bind to the promoter sequence of the target gene, or the ability to bind to or not bind to transcription factors.
- 30 • inhibition or stimulation of growth of a reporter cell such as a reporter cell at a particular physiological stage. This reporter cell may be selected from the group consisting of bacteria, fungi, protozoa, helminth, algae, plants, invertebrates, vertebrates, mammalian cells, somatic human cells, pathogenic microorganisms, agricultural pests, cells infected by an intracellular pathogen, virus-infected cells,
- 35

tumor cells. The reporter cell may also be a whole live organism, e.g., bacteria, fungi, protozoa, algae, plants, invertebrates, insects, tardigrada, parasites, agricultural pests.

5 Preferably the invention comprises selection of cells meeting a predetermined value of more than one parameter, such as selection of cells meeting a predetermined value of each parameter. In early rounds of screening it may be chosen to select cells meeting one or a few of several selection criteria and in later rounds of screening cells meeting all selection criteria are often selected as illustrated in
10 Figure 1.

Any number of screens may be performed on the cells simultaneously. For example one may screen for at least 3 parameters related to the two or more functionalities. One may also screen for at least 4 parameters related to the two or more
15 functionalities. Higher numbers are also possible, so that the method comprises performing at least one screening for at least 5 parameters related to the two or more functionalities, such as at least 6 parameters, for example at least 7 parameters, such as at least 8 parameters, for example at least 9 parameters, such as at least 10 parameters, for example at least 15 parameters, such as at least 20
20 parameters, for example at least 25 parameters, such as at least 50 parameters.

The type and strength of the selection criteria/criterion may be changed and/or increased for at least some of the repeats as described further below.

25 Another aspect of the invention relates to optimising compounds using a method for evolving a cell producing at least one compound, said compound having two or more predetermined functionalities, said method comprising the steps of

a) providing a composition of cells, said composition of cells comprising cells with at
30 least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition containing different heterologous expressible nucleotide sequences, said cells being denoted producer cells,

- b) performing one screening of said population of cells for at least 2 parameters related to the functionalities, and determining a selection criterion for each parameter,
- 5 c) selecting cells meeting at least one predetermined selection criterion,
- d) combining expressible nucleotide sequences of the selected cells with expressible nucleotide sequences from another composition of cells, thereby obtaining at least one new composition of cells, said new composition of cells
- 10 comprising cells with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition containing different heterologous expressible nucleotide sequences,
- 15 e) optionally repeating steps b) to d) until at least one cell has acquired a compound having the at least two predetermined functionalities.

The evolution methods according to the present invention combine the potential for evolution of cells based on assembly or insertion of a large collection of

20 heterologous genes into artificial chromosomes vectors that can be inserted into host cells for co-ordinated expression of the genes located on the artificial chromosomes. The expressed genes interact with each other and with the genes of the host cells and create novel or modified synthetic pathways. The heterologous genes are combined with other heterologous genes from other host cells (and as the

25 case may be from other sources) in a stepwise evolution of the cells to acquire the ability to produce a compound fulfilling the selection criteria.

The term "expressible sequence" is used with its normal meaning, i.e. a sequence capable of being expressed in the host cells in question.

30

In step d) the combination of expressible sequences may be combined in a one-step process, or by a process of several steps of mixing or combining the expressible sequences, independent of whether the combination relates to combination of expressible sequences as such or combination of expression cassettes or

35 combination of chromosomes.

Step e) may be repeated until cells having the desired functionalities are obtained. Thereby step e) may be repeated from 0 to at least 200 times, preferably from 0 to 150 times, such as from 0 to 100 times, such as from 0 to 80 times, such as from 0 to 60 times, such as from 0 to 20 times.

The screening functionality is the functionality during the screening rounds. The screening functionality is normally different from the desired final functionality, but in some embodiments the screening functionality is identical with the desired functionality. The screening functionality is also referred to as the predetermined functionality in the present context.

The said another composition of cells may comprise cells that contain expressible nucleotide sequences likely to confer at least one of the functionalities to the cells in order to increase the likelihood of reaching the evolution target in as few rounds as possible. The another composition of cells may also previously have been screened for a third functionality, or said another composition of cells may comprise cells capable of expressing at least one predetermined protein/enzyme or synthesising at least one predetermined compound or substance. Further, said another composition of cells may be chosen at random or may be chosen to contain genes homologous to the genes contributing to the desired functionality or it may be chosen from expression states known to produce compounds with at least one of the desired functionalities. Said another composition may also be the first composition, resulting in mixing of heterologous expressible nucleotide sequences within the same population leading to cells with novel combinations of heterologous expressible nucleotide sequences.

In a further aspect the invention relates to a screening system comprising a producer cell and at least two reporter systems, wherein each of the reporter systems is directed to a parameter related to a functionality of one compound produced by the cell.

The screening system can be used for multiple parameter screening methods and evolution methods according to the invention

The physical layout of the screening system may be in the form of a gel droplet together with the at least two reporter systems. It may also be a cell in a semi-solid or a liquid environment together with the at least two reporter systems. Further examples of the physical layout of the screening system are disclosed in the detailed description part of the present invention.

In a further aspect the invention relates to a method for generation of optimised lead compounds, said method comprising screening a composition of producer cells for at least two parameters related to at least two predetermined functionalities, said composition of cells comprising cells each with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition containing different heterologous expressible nucleotide sequences.

By optimised lead compounds is meant that the compounds have more than one predetermined functionality. Traditionally, lead compounds are defined as such if they just have activity against a pharmacological target. By this method lead compounds are identified together with the cells capable of synthesising the lead compounds and as the lead compounds are screened for two or more functionalities they have a higher chance of becoming e.g. a drug. As explained above, this method also speeds up the process of developing lead compounds.

Preferably the lead compounds are drug lead compounds and at least one parameter is related to absorption, distribution, metabolism, excretion or toxicity and at least one further parameter is related to activity against a pharmacological target.

Throughout the present invention it is intended that screening for two or more functionalities also includes the possibility of screening the cells for two closely related functionalities at the same time, such as using two assays for the same enzyme, it being understood that every assay is specific and the activity measured in two closely related assays are different. However, preferably the two or more functionalities relate to more different functions.

Definitions

One screening: In the present context the term “one screening” means one simultaneous screening, exemplified by having at least two different assay systems, one for each parameter, simultaneously together with the cell, as opposed to first screening for one parameter and then screening for another parameter. Therefore,
5 one screening means that one cell is subjected to two different screening assays at the same time.

Reporter system: In the present context the term “reporter system” is used to describe the output of an assay for one functionality. A reporter system produces a detectable readout, preferably a fluorescent readout. If different reporter systems
10 are used, each produces a different (preferably fluorescent) readout. Each cell also contains a number of heterologous controllable expressible nucleotide sequences. These expressible sequences enable the cell to produce multiple new compounds. The compounds can then interact with the different reporter systems and lead to the
15 production of fluorescent readouts.

Screening unit: In the present context the term “screening unit” is used to describe a microenvironment wherein the compound and the reporter systems may be brought in contact with each other for facilitating the interactions necessary for the method of
20 the invention.

Expressible nucleotide sequence: a nucleotide sequence capable of being transcribed and optionally translated in the relevant host cell species.

25 Oligonucleotides

Any fragment of nucleic acids having approximately from 2 to 10000 nucleic acids.

Restriction site

For the purposes of the present invention the abbreviation RS_n ($n=1,2,3$, etc) is
30 used to designate a nucleotide sequence comprising a restriction site. A restriction site is defined by a recognition sequence and a cleavage site. The cleavage site may be located within or outside the recognition sequence. The abbreviation “ rs_1 ” or “ rs_2 ” is used to designate the two ends of a restriction site after cleavage. The sequence “ rs_1 - rs_2 ” together designate a complete restriction site.

35

The cleavage site of a restriction site may leave a double stranded polynucleotide sequence with either blunt or sticky ends. Thus, "rs₁" or "rs₂" may designate either a blunt or a sticky end.

5 In the notation used throughout the present invention, formulae like:

RS1-RS2-SP-PR-X-TR-SP-RS2-RS1

should be interpreted to mean that the individual sequences follow in the order specified. This does not exclude that part of the recognition sequence of e.g. RS2 overlap with the spacer sequence, but it is a strict requirement that all the items
10 except RS1 and RS1' are functional and remain functional after cleavage and re-assembly. Furthermore, the formulae do not exclude the possibility of having additional sequences inserted between the listed items. For example introns can be inserted as described in the invention below and further spacer sequences can be inserted between RS1 and RS2 and between TR and RS2. Important is that the
15 sequences remain functional.

Furthermore, when reference is made to the size of the restriction site and/or to specific bases within it, only the bases in the recognition sequence are referred to.

20 Expression state

An expression state is a state in any specific tissue of any individual organism at any one time. Any change in conditions leading to changes in gene expression leads to another expression state. Different expression states are found in different individuals, in different species but they may also be found in different organs in the
25 same species or individual, and in different tissue types in the same species or individual. Different expression states may also be obtained in the same organ or tissue in any one species or individual by exposing the tissues or organs to different environmental conditions comprising but not limited to changes in age, disease, infection, drought, humidity, salinity, exposure to xenobiotics, physiological effectors,
30 temperature, pressure, pH, light, gaseous environment, chemicals such as toxins.

Artificial chromosome

As used herein, an artificial chromosome (AC) is a piece of DNA that can stably replicate and segregate alongside endogenous chromosomes. For eukaryotes the
35 artificial chromosome may also be described as a nucleotide sequence of

substantial length comprising a functional centromer, functional telomeres, and at least one autonomous replicating sequence. It has the capacity to accommodate and express heterologous genes inserted therein. It is referred to as a mammalian artificial chromosome (MAC) when it contains an active mammalian centromere.

5 Plant artificial chromosome and insect artificial chromosome (BUGAC) refer to chromosomes that include plant and insect centromeres, respectively. A human artificial chromosome (HAC) refers to a chromosome that includes human centromeres, AVACs refer to avian artificial chromosomes. A yeast artificial chromosome (YAC) refers to chromosomes are functional in yeast, such as
10 chromosomes that include a yeast centromere. The artificial chromosomes may be linear or circular.

As used herein, stable maintenance of chromosomes occurs when at least about 85%, preferably 90%, more preferably 95%, more preferably 99% of the cells retain
15 the chromosome. Stability is measured in the presence of a selective agent. Preferably these chromosomes are also maintained in the absence of a selective agent. Stable chromosomes also retain their structure during cell culturing, suffering neither intrachromosomal nor interchromosomal rearrangements.

20 Producer species: a species of cell with two or more heterologous expressible nucleotide sequences contained with expression cassettes.

Detailed description of the drawings

25 Fig. 1 shows an example of multiple parameter screening for compounds synthesised by cells. In the example each cell was engineered with 3 different reporter systems. Each reporter system produces a different fluorescent readout. Each cell also comprises a number of heterologous expressible nucleotide sequences. These heterologous nucleotide sequences enable the cell to produce
30 multiple new compounds. The compounds can interact with the reporter systems and lead to fluorescent readout(s). In the specific example, compounds that inhibit Cox-2 and NF- κ B and do not inhibit Cox1 are desired. In the specific example, it is shown that in early rounds, cells that meet one, two or all three of the criteria are selected. In later rounds, only cells that fit all the selection criteria are selected.

Fig. 2 shows an example of a multiple parameter screen setup for novel antibacterials. It includes *S. aureus* growth inhibition, DNA Polymerase III inhibition and P450 non-inhibition assays. The screen is assembled by, for example, transforming a library of producer strains with GFP reporter systems for the non-inhibition of a few selected human P450s and for inhibition of recombinant *Bacillus subtilis* DNA Pol III. The library is then plated and overlaid with an MRSA (Methicillin-resistant *Staphylococcus aureus*) strain. The compounds have to cross the producer's cell wall and reach the MRSA strain thus the screen will also select for compounds that have a reasonable solubility profile. Producer cells in zones cleared of MRSA cells and which produce the desired combination of fluorescent colours are selected.

Fig. 3A illustrates a multiple parameter screen setup for cancer chemoprotectants. In the assay, a producer species library is gel encapsulated so that on average each capsule has 1 producer cell. The cells in the droplets are then allowed to grow for a few generations in order to have multiple copies of the producer species and thus more compound being produced. These clonal cell lines are then double gel encapsulated with a permeabilised yeast expressing human DNA topoisomerase II other than its native gene. The gel droplet environment contains a topo II poison and a marker for the specific double strand breaks produced by this enzyme. Gel droplets where yeasts in both inner and outer droplet have survived and that are not stained are selected.

Fig. 3B shows a multiple parameter screen set-up for novel chemotherapy agents that are selective DNA topoisomerase II poisons.

Fig. 4 shows a multiple parameter screen set up where the gel encapsulation of a producer species library reporting RXR-RXR activation with a mammalian cell line reporting RXR α -PPAR γ activation. Gel droplets that indicate RXR α -PPAR γ activation but not RXR-RXR are selected.

Fig. 5 shows an example of a multiple parameter screen for absorption and a pharmacological activity. By using a dual culture system and timing the time of cell selection, it is possible to select producer cells that have the desired pharmacological activity and a good absorption profile.

Fig. 6 shows an example of a screening system which minimises the number of false positives generated by compounds that are rapidly metabolised by the human drug metabolising enzymes (DMEs) and also leads to the discovery of compounds that are active after being metabolised and which would otherwise remain undiscovered.

Fig. 7 shows a schematic representation of a screening system of the present invention to evaluate target activity, metabolism by DMEs and cytotoxicity: Using a double gel encapsulation system where in the first droplet are clonal lines of the producer species transformed with the pharmacological target and DMEs, and in the second droplet are hepatocytes, it is possible to screen for target activity, DME metabolism and hepatotoxicity simultaneously.

Fig. 8 shows a flow chart of the steps leading from an expression state to incorporation of the expressible nucleotide sequences in an entry library (a nucleotide library according to the invention).

Fig. 9 shows a flow chart of the steps leading from an entry library comprising expressible nucleotide sequences to evolvable artificial chromosomes (EVAC) transformed into an appropriate host cell. Fig. 9a shows one way of producing the EVACs which includes concatenation, size selection and insertion into an artificial chromosome vector. Fig. 9b shows a one step procedure for concatenation and ligation of vector arms to obtain EVACs.

Fig. 10 shows a model entry vector. MCS is a multi cloning site for inserting expressible nucleotide sequences. Amp R is the gene for ampicillin resistance. Col E is the origin of replication in E. coli. R1 and R2 are restriction enzyme recognition sites.

Fig. 11 shows an example of an entry vector according to the invention, EVE4. MET25 is a promoter, ADH1 is a terminator, f1 is an origin of replication for filamentous phages, e.g. M13. Spacer 1 and spacer 2 are constituted by a few nucleotides deriving from the multiple cloning site, MCS, SclI and Ascl are restriction enzyme recognition sites. Other abbreviations, see Fig. 10. The sequence of the vector is set forth in SEQ ID NO 1.

Fig 12 shows an example of an entry vector according to the invention, EVE5. CUP1 is a promoter, ADH1 is a terminator, f1 is an origin of replication for filamentous phages, e.g. M13. Spacer 1 and spacer 2 are constituted by a few nucleotides deriving from the multiple cloning site, MCS, SclI and Ascl are restriction enzyme recognition sites. Other abbreviations, see Fig. 10. The sequence of the vector is set forth in SEQ ID NO 2.

Fig 13 shows an example of an entry vector according to the invention, EVE8. CUP1 is a promoter, ADH1 is a terminator, f1 is an origin of replication for filamentous phages, e.g. M13. Spacer3 is a 550 bp fragment of lambda phage DNA fragment. Spacer4 is a ARS1 sequence from yeast. SclI and Ascl are restriction enzyme recognition sites. Other abbreviations, see Fig. 10. The sequence of the vector is set forth in SEQ ID NO 3.

Fig. 14 shows an example of an entry vector according to the invention, EVE9. Met25 is a promoter, ADH1 is a terminator. Spacer 5 and 6 are lambda phage DNA. The nucleotide sequence of the vector is set forth in SEQ ID NO 5.

Fig. 15 shows a vector (pYAC4-Ascl) for providing arms for an evolvable artificial chromosome (EVAC) into which a concatemer according to the invention can be cloned. TRP1, URA3, and HIS3 are yeast auxotrophic marker genes, and AmpR is an E. coli antibiotic marker gene. CEN4 is a centromere and TEL are telomeres. ARS1 and PMB1 allow replication in yeast and E. coli respectively. BamH I and Asc I are restriction enzyme recognition sites. The nucleotide sequence of the vector is set forth in SEQ ID NO 4.

Fig. 16. shows the general concatenation strategy. On the left is shown a circular entry vector with restriction sites, spacers, promoter, expressible nucleotide sequence and terminator. These are excised and ligated randomly.

Lane	F/Y
1	100/1
2	50/1
3	20/1
4	10/1
5	5/1

6	2/1
7	1/1
8	1/2
9	1/5

Legend: Lane M: molecular weight marker, λ -phage DNA digested w. Pst1. Lanes 1-9, concatenation reactions. Ratio of fragments to yac-arms(F/Y) as in table.

5 Fig 17a and 17b. illustrates the integration of concatenation with synthesis of evolvable artificial chromosomes and how concatemer size can be controlled by controlling the ratio of vector arms to expression cassettes, as described in example 18.

10 Fig 18. EVAC gel Legend: PFGE of EVAC containing clones :
 Lanes. a: Yeast DNA PFGE markers(strain YNN295), b: lambda ladder, c: non-transformed host yeast, 1 – 9 : EVAC containing clones. EVACs in size range 1400-1600 kb. Lane 2 shows a clone containing 2 EVACs sized ~1500 kb and ~550 kb respectively. The 550kb EVAC is comigrating with the 564kb yeast chromosome
 15 and is resulting in an increased intensity of the band at 564 kb relative to the other bands in the lane. Arrows point up to EVAC bands.

Fig. 19 shows an example of generation of an EVAC containing cell population. EVACs (Evolvable Artificial Chromosome) are artificial chromosomes composed of
 20 concatemers of expression cassettes containing heterologous DNA, so that each gene is under the control of an externally controllable promoter. Large numbers of heterologous genes from multiple sources can thus be combined in a single host cell.

25 Fig. 20 shows the general principle for screening EVAC containing cell populations. The cell population is amplified and subjected to a panel of screens that are relevant to a desired functionality. Positive subpopulations are selected.

Fig. 21 shows how cell populations evolve through a tiered set of selection condi-
 30 tions, always taking the best performing cell populations further in the process until an optimal functionality/property is evolved.

Fig. 22 shows a general screening strategy. Independent populations are subjected to the same set of screens, and genetic material from the different selected sub-populations is combined together with novel genetic diversity introduced between selection rounds.

5

Fig. 23 shows physical remixing of EVACs. EVACs are isolated from the host and used for transformation of either empty host cells or for transformation of host cells already containing EVACS to obtain new combinations of EVACs in each host cell.

10

Fig. 24 shows an example of controllable gene expression in a cell population containing EVACs enriched in genes that code for carotenoid synthetic enzymes. The expression cassettes contain either a Met 25 or a CUP I promoter. Orange and red colonies are obtained as a function of the promoter activation. Intensity of colour and number of coloured colonies increases in the following order: CUP + Met > CUP > Met. Uninduced colonies are white.

15

Detailed Description of the Invention

20

The following provides a background description on how to apply the screening methods according to the invention to evolve cells that produce compounds with multiple functionalities.

25

The screening and/or evolution may lead to the production of novel optimised molecules as well as production at various scales of compounds of commercial value.

30

Thus, by "Evolution of a cell" is meant change of a cell's phenotype towards a novel phenotype due to expression of a novel combination of genes. By "evolution of a composition" is meant change of the properties of a composition due to a novel combination of cells expressing a novel combination of genes. The novel combinations are selected using the selection methods of the current invention.

35

In seeking to evolve molecules with defined pharmaceutical, industrial, nutritional or other properties one must have a method of selecting for those genetic patterns that encode for phenotypes that are consistent with these properties.

Each cell in a cell population, given that it is genetically different from other cells, has an intrinsic variability that can potentially express itself in one or more ways. For the purposes of the current invention the term Output shall be taken to mean a property of the cell that is consequent to the expression of one or more expression cassettes. Optionally the property may be consequent to both the expression of one or more expression cassettes and the expression of a certain set of host genes.

Outputs can be measured according to various different criteria. These criteria may be directly or indirectly linked to the functional or structural properties that are being optimised. Alternatively they may be inversely linked to functional or structural properties that are not desired.

Outputs can be measured either directly or by means of a reporter construct. For the purposes of this document the term Reporter Construct shall be taken to mean a genetic or molecular device for measuring whether a given cell or subset of cells in a cell population vary in respect of a given output from other cells or subsets of cells in the cell population. Example reporter constructs include a genetic construct that produces a fluorescent protein in response to the activation of a transcription factor. Another example of a reporter construct is a coloured/fluorescent enzyme substrate, to which an enzyme is added that converts the substrate to another molecule with a different colour/fluorescence. Similarly the reporter system could be an enzyme converting a substrate into a coloured/fluorescent product. Should the cell produce an output that inhibits the enzyme, the colour change will not occur.

Other reporter systems could include without limitation the survival of cells subjected to the selection criteria, cells able to metabolise a predetermined substance, cells able to produce a substance that preferentially absorbs electromagnetic radiation at one or more frequencies, cells having enzymatic efficacy in the media etc.

The term Proximal shall be taken to mean a location that is either within the same cell as the expression construct or which is sufficiently close to said cell such that the concentration of a molecule or molecules diffusing from an intact or lysed cell, or being actively pumped from the cell, is at least one picomole in the vicinity of the location

Reporter constructs can be placed proximal to a cell either before or after the expression construct have been engineered into the cell. Methods of incorporating the reporter construct into a proximal location include but are not limited to standard transformation techniques, the mating of two different yeast mating types, or systems providing physical proximity between cell and reporter construct, for example gel microdroplet co-encapsulation of cell and reporter construct.

Outputs of cells that may be measured either by proximal reporter constructs or by other means include, but are not limited to:

- Novel spectral properties
- Induced cytochrome oxidase activity
- Changed size, morphology, stickiness or adhesive properties or lack thereof
- Superior growth
- Ability to grow on substrates they cannot normally grow on
- Ability to grow in the presence of a toxin
- Ability to grow on sublethal substrates
- Ability to grow in the absence of normal essential requirements
- Ability to grow on media comprising one or more inhibitors
- Ability to grow under changed physical conditions, such as temperature, osmolarity, electromagnetic radiation including light of certain wavelengths.
- Ability to grow under magnetic field of certain force.
- Secretion or the lack of it from the cell
- The inhibition or prevention of inhibition of an enzyme
- The activation of a receptor.
- The prevention of an activating molecule binding to a receptor.
- The inhibition or promotion of binding of small molecules or proteins to nucleic acid or peptide sequences.
- The inhibition or promotion of transcription or translation of post translational processing.
- Changes in the transport or localisation of molecules within the cell or within organelles.
- Changes in the DNA content or morphology of the cell.

- The production of small molecules with certain properties that allow their selective isolation (e.g. all the chromatography principles available to the skilled practitioner).
- The production of small molecules with certain spectroscopic properties (defined broadly to include visible light, microwaves, IR, UV, X-ray, etc.).
- Changes in the morphology of the cell, including the prevention or promotion of cell differentiation.
- The induction of apoptotic pathways.
- Chemical indicator.

10

MULTIPLE PARAMETER SCREENING

For a compound to be useable as a drug it must fulfil multiple functional requirements. It must interact with the target(s) and affect the function of the target in the desired manner. At the same time it should not interact with any other (often similar) targets or have major non-specific effects. Further, it must have the right physical-chemical parameters and be metabolised by the body in an acceptable manner.

Because of this intrinsic difficulty and complexity, the process of discovering and developing drugs has a very poor success rate and is extremely expensive (\$600mn per successful compound) and very time consuming (c. 8-12 years from discovery to clinic). Only c. 1 in 15 primary screens produce a compound that makes it into pre-clinical development and only 1 in 10 of these compounds then make it to market. The average pharmaceutical company spends 250 man-years of research and development effort for every compound that enters the clinic. Most pharmaceutical companies are, in consequence, failing to launch new drugs at the rate they require to satisfy their investors.

An alternative to the current process is the evolution of small molecules compounds towards multiple properties simultaneously, with these properties being related, either directly or indirectly to the therapeutic target(s) the small molecule has to interact with, the targets it should not interfere with, the ADMET properties it should fulfil, etc.

Multiple Pharmacological Activities

Due to the vast number of known targets and relationships between those targets that are currently known, it is not in the scope of the present invention to describe all know targets and their correlations. Table 1 discloses a list of relevant pharmacol-
 5 ological targets. The list is included merely to illustrate examples of targets and is not to be interpreted as limiting the scope of the invention.

Table 1: Drug targets

10

3 β hydroxysteroid dehydrogenase
 3-hydroxy-3-methylglutaryl coenzyme A
 5-adenosyl homocysteine hydrolase
 5-HT₃ receptor
 5-HT₄ receptor
 23S rRNA of the 50S ribosomal unit
 30S rRNA from 50S ribosomal unit
 50S ribosomal unit binding site

 α 2 antiplasmin
 α -adrenergic receptor
 α -subunit of Na⁺/K⁺ ATPase (3 isoforms)
 α -amylase
 α -glucosidase
 ACTH receptor
 Adenosine deaminase
 Adrenocortical steroid synthesis
 Adrenocorticosteroid receptor
 Adrenergic receptor β ₁, β ₂
 Adrenocorticotrophic hormone
 Androgen receptor
 Angiotensin-converting enzyme (ACE)
 Angiotensin II formation
 Angiotensin II receptor
 Antiplatelet/antithrombotic agent
 Arginine vasopressin receptor
 Angiotensin receptors, AT1, AT2
 ATP-sensitive K⁺ channel
 Antigcoagulant protein C
 Antigcoagulant protein S
 Androgen receptor
 Apoptosis
 Aminoacyl tRNA site on 30S ribosomal unit (tetracycline)
 Acetylcholinesterase
 Adrenergic receptors α ₁, α ₂, β ₁, β ₂, β ₃
 Aromatase
 ATP sensitive K⁺ channels
 Ascorbic acid

β -amyloid
 β -adrenergic receptor
 β -lactamase
 β -subunit of DNA-dependent RNA polymerase
 β -adrenergic receptors, b1
 β -tubulin subunit of microtubules
Benzodiazepine receptor
Butyrylcholinesterase
Bradykinin receptors, B₁, and B₂

Carbonic anhydrase, type IV, II
Ca²⁺ channel
Ca²⁺ channel, Voltage-activated T-type
Catechol-O-methyltransferase
Calcitonin
Cell surface receptors for sulfonylureas on pancreatic β cells
Cell surface receptors for glitinides on pancreatic β cells
Cholecystokinin (CCK_A, CCK_B)
Choline acetyltransferase
Cholinesterase
Carnitine
Calcineurin
Corticosteroid nuclear receptor
Cyclophilin, cyclosporin binding protein
CD₃ glycoprotein on T lymphocytes
CD33 receptor
CD20 receptor
CG-rich DNA (actinomycin)
Coagulation factor II, VII, IX, X
Corticosteroid adrenocorticotropin receptors
Cyclooxygenase 1, 2 (COX-1, COX-2)
Cyclic nucleotide phosphodiesterase
Cyclooxygenase
Cytochrome P450 reductase
Cytochrome P450 11 β (11 β hydroxylase)
Cytochrome P450 17 α C17-20 lyase
Cytochrome P450 aldo, aldosterone synthase
Cytochrome P450 side chain cleavage (scc) enzyme
Cytochrome P450-dependent sterol 14 α -demethylase

D-alanyl D-alanine synthetase
Dihydropteroate synthetase
Deoxycytidine kinase
Dihydroorotate dehydrogenase
Dihydrofolate reductase
Dopamine D1-D5 receptors
DNA chain elongation factor
DNA cross-linking
DNA-dependent RNA polymerase
DNA gyrase, subunit a
DNA methylation
DNA polymerases I+III

DNA primase
 DNA topoisomerase
 DNA alkylation
 DNA topoisomerase IV
 DNA alkylation (oxamniquine)

Erythropoietin
 Endo- β -d-glucuronidase
 Estrogen receptor

Factors VII; VIII
 Fusion protein (respiratory syncytial virus)
 FKBP, tacrolimus binding protein, FK506 binding protein
 Folic acid
 Follicle-stimulating hormone (FSH)
 FSH receptor

Glycerol phosphate oxidase
 GABA_A receptor (6 α variants, 3 β , 2 δ , 3 γ variants)
 GABA transaminase
 GABA_A-associated ion channel
 Glutamic acid decarboxylase
 Glutamate/aspartate receptors, AMPA, GLU 1-4, KA, GLU 5-7, NMDA 1,2_{A-D},
 mGLU 1-7
 Glycinamide ribonucleotide transformylase
 Granulocyte colony-stimulating factor receptor
 GHRH receptor
Glucagon receptor
 Glucoamylase
 Glucocorticoid receptor (GR)
 GnRH receptor
 Gonadotropin releasing hormone (GnHR)
 Guanylyl kinase
 G-protein coupled adenosine receptor
 Ganglionic adrenergic neurons/norepinephrine transporter
 Guanylate cyclase (nitroprusside)
 Guanylyl cyclase (NO)
 Granulocyte colony-stimulating factor
 Granulocyte-macrophage colony-stimulating factor
 Growth hormone receptor
 Growth hormone-releasing hormone (GHRH)
 Glycine receptor α , β

5

H⁺, K⁺ ATPase, proton pump
 H₁ histamine receptor
 H₂ histamine receptor
 HCl secretion by gastric cells
 Helicase
 HIV Protease
 HSV thymidine kinase
 Hemoglobin protease

Heparin antagonist
 Hypoxanthine-guanine phosphoribosyl transferase
Her-2 receptor
 Histamine receptors H₁, H₂, H₃
 Hepatic sulfotransferase as a catalyst

Intercellular adhesion molecule 1
 Interleukin 1 receptor
 Interleukin (IL-1, -2, -3, -4, -5, -6, -7, -8, -9, -10, -11, -12)
 Interleukin-2 receptor
 IGF-1 receptor, IGF-2 receptor
 Iodothyronine-59-deiodinase, type 1, type 2
 Influenza A virus M₂ protein
 Inosine 5' phosphatedehydrogenase
 Insulin-like growth factor 1
 Interleukin-2 receptor
 Inosinate dehydrogenase
 Interferon α
 Interferon α receptor
 Inosine monophosphate dehydrogenase
 Integrase
 Interferon α
 Interferon α receptor
 Interferon γ
 Insulin
 Insulin-like growth factor (IGF-1, IGF-2)
 Insulin receptor, α and β subunits
 Insulin transporter

Kallikrein, aprotinin, C-esterase, α 2 macroglobulin
 Kinin

L-alanyl racemase
 L-aromatic amino acid decarboxylase
 L-type voltage-sensitive Ca²⁺ channel
 Leukocyte integrins
 Leukotriene A hydrolase
 Leukotriene B₄ receptor
 Leukotriene C₄ receptor
 Leukotriene C synthase
 Leukotriene D₄/E₄ receptor
 Lipocortin (protein), inhibits phospholipase A₂
 Lipoxygenases (12-lipoxygenase (platelets), 5-lipoxygenase (leukocytes))
 LH/choriogonadotropin (CG) receptor
 Luteinizing hormone (LH)
 Lactamase
 Lipoprotein lipase

5

M₁ receptor, muscarinic cholinergic
 μ and δ receptor in gastrointestinal tract
 Macrophage colony-stimulating factor

Microbial dihydrofolate reductase
 Microtubular protein
 Mineralocorticoid receptor
 Mineralocorticoid receptor (MR)
 Monoamine oxidase (MAO)-A
 Monoamine oxidase (MAO)-B
 Muscarinic receptor, M₁, 3 subunits
 Muscarinic receptor, M₂, 3 subunits
 Muscarinic receptor, M₃, 3 subunits
 Muscarinic receptor, M₄, 3 subunits
 Mycobacterial RNA polymerase

N-acyl hydrolase
 Na⁺ channel, α 1, β 1, β 3
 Na⁺ channel α , β , γ
 Na⁺/Cl-symporter
 Na⁺/K⁺/2Cl-symporter
 Niacin receptor
 Nicotinic acid
 Nicotinic receptor
 Nicotinic cholinergic receptors, muscle N_M α , β , δ , γ , ϵ
 Nicotinic cholinergic receptors, neuronal, N_N α 2, α 3, α 4, α 5, α 6, α 7, α 8, α 9,
 β 2, β 3, β 4
 Neuramidase
 Neuropeptide Y, Y1, Y2 receptors
 Noradrenaline transporter

Opioid receptors μ ₁₋₂, δ ₁₋₂, κ ₁₋₃
 Oxytocin & receptor

Platelet-derived growth factor
 Parathyroid hormone (PTH)
 Peroxidase
 Progesterone receptor
 Prolactin
 Prolactin receptor
 Parasite β -tubulin
 Parasite dihydrofolate reductase
 Parasite glutamate gated Cl⁻ channel
 Penicillin-binding protein 1a (PBP 1a, 1b), transpeptidase
 PBP 2a, 2b
 PBP 3, 4, 5, 6, 7
 Platelet glycoprotein IIb/IIIa (fibrinogen receptor)
 Plasma protein transferrin (β 1 glycoprotein)
 Pyridoxine receptor
 Penicilloyl enzyme
 Peptidyl site of the 50S ribosomal unit
 Primase
 Phosphodiesterase (type IV, cyclic nucleotide phosphodiesterase)
 Phospholipase A₂, C
 Platelet-activating factor
 Prostacyclin synthase

Plasmodial heme polymerase
 Progesterone receptor
 Pyridoxine
 Phospholipase C β
 Purine receptors, P1 (A_{1,2a,2b,3}), P_{2X}, P_{2Y}
 Peroxisome proliferator-activated receptor
 Pancrelipase
 Potassium channel
 Prostaglandin 15-OH dehydrogenase
 Prostaglandin D-DP receptor
 Prostaglandin E1, E2, E3-EP receptor
 Prostaglandin F-FP receptor
 Prostaglandin I₂-IP receptor
 Prostaglandin I₂ (PGI₂) receptor
 Prostaglandin F₂ receptor
 Prostaglandin synthetase
 Prostaglandin I₂ receptor

Reverse transcriptase
 Ribosomal protein from 50S ribosomal unit (streptomycin)
 Rh 0
 Riboflavin receptor
 Retinoic acid α , X receptors
 Ribonucleoside diphosphate reductase
 Ribonucleotide reductase

Somatostatin
 Somatostatin receptors, several
 Steroid 5 α reductase 1, 2
 Sucrase
 Squalene epoxidase
 Stem cell factor, c-kit ligand
 Serotonin receptors (5-HT) 5-HT_{1A-F}, 5-HT_{2A-C}, 5-HT₃, 5-HT₄₋₇
 Succinic semialdehyde dehydrogenase
 Spindle formation
 Scission of DNA
 Secretion of vasopressin K receptor

Topoisomerase I, II, III, IV
 Tubulin
 Thrombopoietin
 Thrombin
 Tissue plasminogen activator
 Thymidylate synthetase
 Tachykinins, NK1, NK2, NK3
 Tryptaminergic receptor
 Thromboxane A₂ TP receptor, platelet and non-platelet
 Thromboxane synthase
 Thyroid-stimulating hormone (TSH) receptor, TR α 1,2, TR β 1,2
 Tumor necrosis factor receptor
 Trypanothione reductase

31

Type I cyclic nucleotide phosphodiesterase
 Type III cyclic AMP phosphodiesterase
 Type V cyclic nucleotide phosphodiesterase
 Transpeptidase
 Thymic lymphocyte antibodies
 Tumour necrosis factor alpha
 Thiamine

Uridine monophosphate pyrophosphorylase

Vascular cellular adhesion molecule 1 receptor
 Vasopressin receptors V_{1a}, V_{1b}, V₂,
 Viral DNA polymerase
 Vitamin A nuclear receptor
 Vitamin E
 Vitamin K & receptor
 Vitamin B₁₂ receptor
 Vitamin D nuclear receptor
 Voltage-activated Ca²⁺ channel, L-type

- 5 Below are examples of diseases and the different targets involved in these diseases and strategies of how to develop optimised compounds. It is also presented in outline examples of how new potential drugs for these targets would be screened and/or evolved using the present invention.

10 **1) Disease Target: Bacterial infections (inhibition of DNA Polymerase III, P450 inhibition and Multi-drug resistance *S. aureus* growth inhibition)**

The widespread emergence of resistance has significantly limited the efficacy of classical antibiotic therapy for bacterial disease. Fuelled largely by the excessive
 15 and often unnecessary use of antibiotics in humans and animals, antibiotic resistance has resulted in increased patient morbidity, mortality and overall cost of health care. Methicillin-resistant *Staphylococcus aureus* (MRSA) is now the most prevalent nosocomial pathogen in the United States, and the enterococci, as opportunistic pathogens, are among the top four causes of nosocomial infection. Indeed, the percentage of enterococcal isolates resistant to essentially every antibiotic, including
 20 vancomycin, continues to increase. Thus a premium is placed upon the discovery of inhibitors that function by a novel or at least different mechanism than currently approved antibiotics, as these would be expected to circumvent current bacterial resistance mechanisms.

S. aureus is a very important human pathogen and has favorable growth characteristics for use in high-throughput screening. Use of an antibiotic-resistant strain will *a priori* select for hits that have activity against a multi-drug resistant strain.

5 DNA Polymerase III is a DNA polymerase-exonuclease (Pol-Exo) that is essential for the replicative DNA synthesis of Gram positive organisms. Since DNA Pol III is essential for the replication of Gram positive bacteria, the inhibition of DNA Pol III offers a specific and alternative way to treat antibiotic resistant gram positive bacteria.

10

Many patients with severe disease may be administered multiple anti-infectives as well as other drugs to treat (non-infectious) underlying disease. In this case, drug classes that are not metabolized via the major P450 liver enzymes are preferable.

15 Desired therapeutic profile:

• *Gram positive-specific:* Systemic administration of agents with a very broad spectrum may have the undesired effect of creating resistance in the normal host Gastrointestinal flora. Therefore, more disease-specific antibiotics might
20 have an advantage in gaining hospital formulary approval and overall wider acceptance.

• *Orally-active:* The ideal drug candidate would be orally-active with additional formulations for intravenous use. Multiple dosing is acceptable however anything
25 approaching continuous infusion requires very careful consideration. Improvement or equivalence with dosing regimens of competitive therapies is important.

• *Safety:* The ideal drug candidate would be microorganism-specific and devoid of significant side-effects and drug interactions within at least 10-fold of C_{max} in the
30 therapeutic dosing range.

Multiple parameter screens:

A multiple parameter screen would thus include *S. aureus* growth inhibition, DNA
35 Polymerase III inhibition and P450 inhibition. A screen could be assembled by, for

example, transforming a library of producer strains with recombinant *Bacillus subtilis* DNA Pol III combined with the inclusion of P450 enzymes and reporter substrates in the surrounding medium. The library would then be plated and overlaid with an MRSA strain. An assay where the compounds have to cross the producer's cell wall and reach the reporter strain will also select for compounds that have a reasonable solubility profile.

Figure 2 exemplifies such a multiple parameter screen where producer cells in zones cleared of MRSA cells and which produce the desired combination of fluorescent colours would be selected.

2) Disease target: Cancer - Inhibition of solid tumour growth and prevention of metastasis (inhibition of NF- κ B, inhibition Cox-2, no inhibition Cox-1)

Cancer is the second leading cause of death in the US, causing one in every four deaths. Existing treatments for surgically inoperable cancers include chemotherapy and radiation treatments. These are highly toxic because they are non selective or at best only partially selective. There exists a critical need for new therapeutics to inhibit tumor growth and prevent metastasis. A premium is placed upon molecules that prevent metastasis and which work through a selective mechanism so as to avoid or minimize side effects.

Nuclear Factor κ B (NF- κ B) is a transcription factor that, by regulating the expression of multiple inflammatory and immune genes, plays a critical role in host defense and several pathogenic processes. Its most common inducible form is composed of the proteins p65 and p50, and usually exists as a molecular complex with one of several inhibitory molecules, the I κ Bs, in the cytoplasm. Proteins that are regulated by NF- κ B include TNF α , IL-1 β , IL-2, IL-6, IL-8, iNOS, COX-2, intercellular adhesion molecule-1 (ICAM-1), vascular-cell adhesion molecule-1 (VCAM-1) and E-selectin (*Cancer J.*, 1998, **4**, S92; *Int. J. Biochem. Cell. Biol.*, 1997, **29**, (6), 867).

Activation of NF- κ B can lead to the synthesis of the inducible form of cyclooxygenase (COX-2). This enzyme has a critical role in the response of tissues to injury or infectious agents and are essential components of the inflammatory response, the ultimate repair of injury, and carcinogenesis. Several population-based studies

have detected a 40-50% decrease in relative risk for colorectal cancer in persons who regularly use Aspirin and other NSAIDs. Attempts to determine the molecular basis for these observations found that both human and animal colorectal tumors express high levels of COX-2, whereas the normal intestinal mucosa has low to undetectable COX-2 expression. These findings led to the hypothesis that COX-2 plays a role in colon cancer growth and progression (*Faseb*, 1998, **12**, 1063). Since Aspirin also inhibits NF- κ B these findings also suggest that inhibiting NF- κ B may prevent tumour growth and progression. Another way in which COX-2 seems to be involved in cancerinogenesis is by protecting cells from apoptosis (*J. Nat. Cancer Inst.*, 1998, **90**, (11), 802). Therefore, inhibition of NF- κ B can help control tumor growth by one further process since it leads to less COX-2 induced protection from apoptosis. Inhibition of NF- κ B also leads to an increase in Tumor Necrosis Factor (TNF) which in turn leads to an increase in apoptosis.

Immense effort is being devoted to developing new molecules that are direct inhibitors of the enzymatic activity of COX-2. However, an alternative approach is to find new agents that can prevent expression of the respective genes coding for the activities since there are already examples that inhibition of a single mediator does not eliminate all symptoms of a disease (*Inflamm. Res.*, 1997, **46**, 282).

Desired therapeutic profile:

- *NF- κ B inhibitor with increased selectivity:* There are several drugs that act by partial inhibition of NF- κ B but they all produce side effects due to interactions with other targets. Any new NF- κ B inhibitor would have to be selective.
- *Selective COX-2 inhibitor with a Cox-2/Cox-1 differential inhibitory activity as low as possible:* Prostanoids that are derived from the COX-1 pathway regulate platelet aggregation via thromboxane A₂, the function and integrity of gut mucosa, and kidney function via prostaglandin E₂ and prostacyclin. Cox-2 is expressed in various cell types, including monocytes, fibroblasts and synovial cells, in response to inflammatory stimuli. Consequently, COX-1 inhibition by NSAIDs is associated with gastrointestinal and renal toxicity, whereas, COX-2 inhibition limits the formation of pro-inflammatory cytokines at the site of the inflammatory response and has anticancer effects.

- *Orally-active*: Given the severity of the medical problem, an orally-active drug would be desired but not essential.

- 5
- *Safety*. The ideal candidate would be selective and devoid of significant side-effects and drug interactions. However again, given the severity of many cancers and lack of therapeutic options, there is significant history of compounds that are less-than-ideal in these aspects.

10 Multiple Parameter Screen:

A multiple parameter screen set up could for example be the double gel encapsulation of a producer species library with 2 different mammalian cell lines. The first gel capsule would contain the producer cell and a mammalian cell reporting NF- κ B and Cox-1 inhibition while the second capsule would contain a second mammalian cell line reporting Cox-2 inhibition. Gel droplets producing the desired fluorescence output would be selected.

15

20 **3) Disease target: Cancer (survival in the presence of DNA Topoisomerase II α poisons, no production of DNA double strand breaks and inhibition of human DNA topoisomerase II activity)**

Chemotherapy is one of the most common approaches to the treatment of cancer. All chemotherapy drugs interfere with cell growth, and they all have some form of side effects. These vary from the highly undesirable to side effects so severe as to prevent further chemotherapy.

25

An underlying problem of chemotherapy is that cancer cells are not that different from normal undifferentiated or fast growing tissues and therefore, killing a cancer cell tends to kill such cells as well. This side effect effectively limits the dose at which the chemotherapeutic can be applied, and hence limits the efficacy that can be achieved. Consequently, there is a need for the development of novel chemotherapeutic agents to overcome these central problems of cancer chemotherapy.

30

The most common way to address the above problems of cancer chemotherapy is to look for compounds or delivery systems that increase the specificity for cancer cells. However an alternative approach is to use compounds that protect vulnerable normal tissue against the proposed chemotherapeutic agent. Such protectants should of course not be harmful to the normal cells and either not reach, or not be functional in the cancer cells. A number of protectant approaches are in clinical use today.

Many chemotherapeutic agents, e.g., Doxorubicin and Etoposide have a large part of their toxicity (and hence clinical utility) due to the specific way in which they "poison" the enzyme Topoisomerase II, an enzyme with a crucial role in the elongation and termination stages of DNA replication. These drugs stabilise an intermediate DNA/enzyme/drug complex, creating double-stranded breaks in the DNA of treated cells. A second class of structures act by blocking the Topoisomerase II catalytic cycle at other points in the cycle and do not create double-stranded DNA breaks. These two types of compounds are antagonists to each other since they stabilise different points in the cycle. If one binds, the other cannot. Therefore, inhibitors of Topo II can be used to offset the effects of Topo II poisons.

Two highly homologous isoforms of mammalian topoisomerase II have been identified in tumor cells, topoisomerase II α (170 kDa) and topoisomerase II β (180 kDa) (Malonne, H. and Atassi, G., *Anti-Cancer Drugs*, 1997, **8**, 811-822). The two isoforms differ in several biochemical and pharmacological properties, such as optimal salt concentration for *in vitro* catalytic activity, thermal stability and sensitivity to teniposide (a non-intercalative DNA topoisomerase II poison). Topoisomerase II α is the major drug target isoform in mammalian cells (Sehested et al, *Cancer Research*, 1998, **58**, 1460-1468).

The discovery of new inhibitors of DNA topoisomerase II would enable the protection of certain vulnerable tissues against Topo II poisons and hence expand the efficacy of existing chemotherapy drugs and reduce side effects.

Desired therapeutic profile:

- *DNA topoisomerase II α inhibitor*: Any new compound would have to be an inhibitor and not a poison of the enzyme.
- 5 • *Reversible inhibition of normal cell growth*: The effects of the drug should only last long enough to off set the effects of the chemotherapeutic agent
- *Orally-active*: Given the severity of the medical problem, an orally-active drug would be desired but probably not essential.
- 10 • *Safety*: The ideal candidate would have modest toxicity such that it does not by itself place an additional toxicity burden on the patient.

Multiple Parameter Screen:

- 15 A multiple parameter screen set-up for DNA topoisomerase II catalytic inhibitors is illustrated in Fig. 3A. In the assay, a producer species library is gel encapsulated so that on average each capsule has 1 cell. Each encapsulated cell is allowed to grow for a few generations in order to establish a clonal cell line. These cell lines are then double gel encapsulated with a permeabilised yeast that relies on a human DNA
- 20 topoisomerase II gene to survive. The gel droplet environment contains a DNA topoisomerase II poison and a stain specific for DNA double strand breaks. Gel droplets where cells have survived in both compartments and that are not stained are selected.
- 25 An improved multiple parameter screen set-up for cancer chemoprotectant is illustrated in Fig. 3B. In the assay, a producer species library is encapsulated so that on average each capsule has 1 cell and is allowed to grow for a few generations. These clonal lines are then double encapsulated with a permeabilised yeast that relies on a human DNA Topo II α to survive. The gel droplet environment contains a
- 30 poison and a DNA double strand break stain. Gel droplets where the yeast cells in the outer layer have survived and that do not fluoresce or are stained are selected.

4) Disease target: Diabetes (ligand activation of RXR α , ligand specific activation of RXR-PPAR γ , adipocyte differentiation).

Type 2 diabetes is one of the most common chronic diseases and is associated with co-morbidities, such as obesity, hypertension, hyperlipidemia and cardiovascular disease.

5

Peroxisome proliferator-activated receptors (PPARs) and retinoid X receptors (RXR) are transcription factors belonging to the family of ligand-inducible nuclear receptors. There are three related but distinct PPARs called PPAR-alpha, PPAR-beta/delta and PPAR-gamma that form heterodimers with RXR. These receptors regulate expression of genes involved in fat and carbohydrate metabolism. RXR is unique among retinoid receptors as it can form homodimers and it can form heterodimers with multiple nuclear receptors including PPARs, retinoic acid receptors (RARs), vitamin D receptor, and thyroid hormone receptor.

10

15

PPAR γ /RXR heterodimer regulates adipogenesis and insulin sensitivity both when activated by PPAR γ ligands and/or RXR ligands. For example, insulin sensitizers, such as the drugs from the thiazolidinedione class (TZDs), exert their antidiabetic effects through a mechanism that involves activation of the gamma isoform of the nuclear receptor (PPAR γ).

20

Activation of RXR α increases activation of PPAR γ and insulin sensitivity. Clinical studies show that co-administration of retinoids (LG100268) +TZDs increases insulin sensitivity and glucose uptake by 60%

25

The retinoid receptors mediate the biological effects of natural and synthetic vitamin A derivatives, such as retinoic acid. RXR ligands interact with many different proteins, including members of the following protein families: RXR, RAR, retinoic acid receptor-related orphan receptor (RZR), cytoplasmic retinoic acid-binding proteins, retinal-binding protein, P-glycoprotein and cytochrome P450. The expression level of each of these proteins is likely to affect the potency and efficacy of retinoids in various cell types.

30

Rexinoids may have undesirable effects mediated by RXR homodimers or heterodimers partners other than PPAR γ . Rexinoids for treating type 2 diabetes should thus be selective for the PPAR γ /RXR heterodimer.

35

Desired therapeutic profile:

- *Selectivity:* RXR agonists should be selective for the PPAR γ /RXR heterodimer.
- *Orally-active:* The ideal drug candidate would be orally-active.
- *Safety:* The ideal drug candidate would be devoid of significant side-effects and drug interactions.

Multiple Parameter Screen:

A multiple parameter screen set up could be the gel encapsulation of a producer species library reporting RXR-RXR activation with a mammalian cell line reporting PPAR γ -RXR activation as well as P450 inhibition. Gel droplets that indicate PPAR γ -RXR activation but not RXR-RXR are selected. Figure 4 exemplifies such a system.

Absorption, Distribution, Metabolism, Excretion & Toxicity (ADMET)

Major reasons for the failure of lead compounds in development often involve inappropriate kinetics or toxicity, thus there is a strong need to obtain the relevant information as early as possible in the discovery process in order to spend as little as possible on inadequate compounds. The pharmaceutical and biotech industries are thus currently focusing on transforming the traditionally very low throughput processes of physicochemical, pharmacokinetic and toxicity optimization studies into high throughput selection methods in order to obtain the relevant information as early in the discovery process as possible.

Through the use of evolutionary strategies and cell based systems, the present invention enables the inclusion of ADMET requirements in the lead generation process and thus reduces significantly the production and screening of thousands of compounds that are not drug like.

Solubility

For drugs to be effective they must be able to reach their targets in effective amounts. In cell free assays the only limitation that exists in this regard is the compound's solubility in the assay buffer. In cell-based assays with intracellular targets, the ability of compounds to diffuse across cell membranes is dependent on their ability to partition into and out of lipid-rich membranes. This process is more efficient when compounds have a certain degree of lipophilicity in addition to being sufficiently water-soluble. If the cell culture medium contains proteins (such as from the presence of fetal calf serum) the degree of binding of the compound to serum proteins influences the freely diffusible fraction of compound and hence the amount available for interaction with the target. The extent of drug binding to serum proteins has a number of important implications in the living organism including transport and distribution.

The present invention uses a host species to produce the compounds. In a preferred embodiment it uses assays external to the producer species. Thus it is an inherent part of the process to evaluate the ability of compounds to diffuse across cell membranes. The presence of medium proteins is also an inherent part of the system.

Another aspect of the invention is the control of the expression or activity of the host's drug resistance pumps. This can be done by placing an externally controllable promoter in front of a sequence coding for a drug resistance pump. This control allows significant secretion of the compounds produced in the first rounds of screening, when the solubility of compounds produced is not a key selection criteria. In later rounds of screening the expression of the pumps can be progressively turned off in order for the compounds that reach the disease targets to have to cross the host's cell membrane and thus have a reasonable solubility profile.

Absorption

30

The preferred route of drug delivery is oral administration. The intestinal membrane permeability is a critical characteristic that determines the extent and rate of drug absorption and ultimately the bioavailability. Other cells which are relevant for drug uptake include epithelial, epidermis, nasal, blood-brain and blood-testis barriers, as

well as the kidney, liver, intestinal epithelial and lung cells, which are also routes for uptake of drugs.

Most models of absorption involve the use of cultured, immortalised cells, which are generally intestinal in nature and which give a good correlation with absorption in vivo. Most notable among them are CaCo-2 cells that derive from a human colon carcinoma cell line or a subclone of the CaCo-2 cell line, TC7. Other useful cell lines for absorption studies are dog kidney cell line, the Madin-Derby Canine kidney cell line (MDCK) and everted intestinal rings and brush-border membrane vesicles (BBMV). These cell lines are grown in a confluent monolayer and used for permeability measurements which are based on the rate of appearance of test compound in the receiver compartment. The apical surface of the monolayer contains microvilli and thus retains many characteristics of the intestinal brush border. Furthermore, the apically located efflux pump, P-glycoprotein, the monocarboxylic acid transporter, the dipeptide transporter, the transporter for large neutral amino acids (LNAA) [Inui K-I, Yamamoto M, Saito H. T, *J Pharmacol Exp Ther*, 1992; **261**: 195-201; Lu S, Guttendorf RJ, Stewart BH, *Pharm Res*, 1994; **11**: S-258.] and metabolic enzymes [Bjorge S, Halehle KL, Homan R, Rose SE, Turluck DA, Wright DS., *Pharm Res*, 1991; **8**: 1441-1443] are all functionally expressed.

Figure 5 shows an example of a multiple parameter screen for absorption and a pharmacological activity. Using a dual culture system and timing the time of cell selection, it is possible to select producer cells that have produced compounds with the desired pharmacological activity and a good absorption profile.

More specifically, one functionality may be screened by culturing the cells in connection with immortalised mammalian cells and detecting the effect of the compound or a metabolite of the compound in a receiver compartment. The cultured immortalised cells can be grown in a confluent monolayer and compounds with desirable permeabilities be selected.

Drugs that inhibit P-glycoprotein can alter the absorption, disposition and elimination of co-administered drugs and can enhance bioavailability or cause unwanted drug-drug interactions. Thus another important aspect of absorption studies is to determine if a compound is a PGP inhibitor by a direct measure of inhibition of PGP-

mediated digoxin transport across polarized human PGP cDNA -expressing LLC-PK1 cell monolayers.

In mammals, the ABC transporters, like MDR1 and MRP1, have a key role in the functioning of the blood-brain and blood-testis barriers, as well as in the kidney, liver, lung, and intestinal epithelial cells. MDR1 is expressed normally on apical membranes of cells derived from excretory tissues, as well as on the luminal surface of cerebral capillary cells (*Gottesman et al., 1993; Cordon-Cardo et al., 1989*). MDR1 and MRP1 are present in the epithelia of the choroid plexus (CP) and both transporters participate in the blood-CSF permeation barrier (*Rao et al., 1999*). MDR1-Pgp contributes to the drug-permeation barrier in cerebral capillary endothelial cells and takes part in elimination of organic cations and xenobiotics from the central nervous system (CNS) (*Rao et al., 1999; Schinkel et al., 1997*). MRP1 contributes to the basolateral broad-specificity drug-permeation barrier in CP, protects this epithelium from xenobiotics and extrudes organic anions and probably also some hydrophobic compounds from the CSF (*Wijnholds et al., 2000*). Some ABC transporters form and regulate specific membrane channels, while others are involved in the elimination of detoxified drug-conjugates, transport of phospholipids or bile acids, and even the initiation of antiviral immune-reaction or specific self-destruction in various cell types. Moreover, members of the ABC transporter family were shown to provide multidrug resistance in pathogenic bacteria and parasites (e.g. *Plasmodium* and *Leishmania* species), while also allowing multixenobiotic resistance (MXR) in a large variety of organisms living in a chemically polluted environment (*Kurelec et al., 1989; 1992*).

In order to predict the penetration of a compound through different pharmacological barriers, a wide range of ABC transporters-compound interactions are also being tested, e.g., Pgp/MDR1, MRP1, MRP2, MDR3, MRP3, MRP5, MRP6, MXR (BCRP, ABCG2).

Metabolism

A drug, once it enters an organism, can experience a variety of biological fates. Drug metabolizing enzymes, including cytochromes P450, (present at high levels in liver, kidney, gut and other organs), can catalyze the chemical conversion of a par-

5 ticular drug to entities (metabolites) which are more aqueous-soluble and more readily excreted than the parent drug from which they were derived. If a parent drug is inherently metabolically unstable, undesirable pharmacokinetic behavior, such as an inappropriately short duration of action or poor oral bioavailability, can be observed. It is therefore, common practice in the industry to gain knowledge about the metabolic stability of lead candidates in order to identify compounds that may turn out to have poor pharmacokinetic profiles.

10 In addition, studies in drug metabolism can address the issue of possible drug-drug interactions, which are closely linked to the safe use of drugs in polytherapies. Most undesirable drug-drug interactions occur when two or more compounds compete for the same drug-metabolizing enzyme. The result is usually altered pharmacokinetics for one or more of the compounds involved, sometimes accounting for compound blood levels which are outside of the therapeutic window. These types of interactions can be foreseen with the assistance of studies of the inhibitory effects of test compounds with specific drug metabolizing enzymes.

20 Various *in vitro* methods are available which are being increasingly incorporated into drug discovery strategies. Among the most popular and widely utilized systems in use today are hepatic microsomes. These preparations retain activity of those enzymes that reside in the smooth endoplasmic reticulum, such as cytochromes P450 (CYP), flavin monooxygenases (FMOs), sulfotransferases, UDP-glycosyl transferases, glutathione transferases and N-acetyl transferases. Isolated hepatocytes appear to retain a broader spectrum of enzymatic activities, including not only reticular systems, but cytosolic and mitochondrial enzymes as well. Liver slices, which like hepatocytes retain a wide array of enzyme activities, are also increasingly used. Furthermore, both hepatocytes and liver slices are capable of assessing of enzyme induction *in vitro*. Isolated heterologous human CYP enzymes have been available for several years, being expressed from cDNA in yeast (*Saccharomyces cerevisiae*), bacterial (*Escherichia coli*), and mammalian (B-lymphoblastoid) cell lines [Ohgiya S, Komori M, Fujitani T, Miura T, Shinriki N, Kamataki T., *Biochem Int*, 1989; **18**: 429-438; Winters DK, Cederbaum AI, *Biochim Biophys Acta* 1992; **1156**: 43-49; Crespi CL, Gonzalez FJ, Steimel DT, Turner TR, Gelboin HV, Penman BW, Langenbach R, *Chem Res Toxicol*, 1991; **4**: 566-572]. These systems have been used to ascertain

whether a compound is a substrate for a particular CYP isozyme and, if so, what metabolite is generated by that enzyme.

5 Assays using recombinant human cytochromes P450, (including CYP2D6 & CYP2C19 that are polymorphically-encoded) as well as assays using isozyme-specific substrate and metabolite combinations in liver microsomal preparations can provide valuable information regarding a test compound's drug-drug interaction potential.

10 In the present invention the generation of small molecules is carried out by host cells that can themselves be transformed with a range of enzymes involved in human metabolism. These minimises the number of false positives generated by compounds that are rapidly metabolised by the human DMEs and also leads to the discovery of compounds that are active after being metabolised and which would otherwise remain undiscovered. (see figure 6).

15 In another aspect of the invention the drug metabolising enzymes are included extracellular to the small molecule producer cell in either cell free or cell based assays. In still another embodiment, some drug metabolising enzyme are included intracellularly and some extracellularly to the small molecule producer cell.

The invention may employ the simultaneous use of 2, 3, 4, 5, 6, 7, 8, 9, 10 or more different drug metabolising enzymes.

25 When using cell based assays, one preferred approach is the use of hepatocytes.

In yet another aspect of the invention reporter systems for activity of the drug metabolising enzyme(s) are included in order to gain information on enzyme inhibition. In yet another aspect of the invention, competition assays for drug-drug interactions can be carried out.

30 In specific cases, some of the drug metabolising enzymes are themselves the disease targets since several of these enzymes are known to be associated with several diseases.

Conceptually, the drug metabolizing enzymes are divided into two groups. Oxidative drug metabolizing enzymes, which include CYP450s and FMOs, catalyze the introduction of an oxygen atom into substrate molecules, generally resulting in hydroxylation or demethylation. The conjugative enzyme families include the UDP-glycosyltransferases (UGTs), glutathione transferases (GSTs), sulfotransferases (SULTs), and N-acetyltransferases (NATs). The conjugative drug metabolizing enzymes catalyze the coupling of endogenous small molecules to xenobiotics that usually results in the formation of soluble compounds that are more readily excreted.

10 *Cytochrome P450s*

Cytochrome P450 proteins in humans are drug metabolizing enzymes and enzymes that are used to make cholesterol, steroids and other important lipids such as prostacyclins and thromboxane A₂. These last two are metabolites of arachidonic acid. Mutations in cytochrome P450 genes or deficiencies of the enzymes are responsible for several human diseases. Induction of some P450s is a risk factor in several cancers since these enzymes can convert procarcinogens to carcinogens.

CYP450 enzymes in the liver catalyze the initial step in the biotransformation of xenobiotic compounds, including most drugs. These enzymes are members of a large family of mixed-function oxidases that catalyze the introduction of an oxygen atom into substrate molecules, often resulting in hydroxylated or dealkylated metabolites. The metabolism takes place in two phases. Phase I is chemical modification to add a functional group that can be used to attach a conjugate. The conjugate makes the modified compound more water soluble so it can be excreted in the urine. Many P450s add a hydroxyl group in a Phase I step of drug metabolism. The hydroxyl then serves as the site for further modifications in Phase 2 drug metabolism.

More than fifty CYP450 isozymes are known to exist in humans and they have been classified into 18 families and 43 subfamilies based on amino acid sequence similarities. Proteins from the same family are greater than 40% identical at the amino acid level, while those in the same subfamily are greater than 55% identical (Nelson, D.R. (1999) *Arch. Biochem. Biophys.* **369**:1-10). In the standard nomenclature, the family is designated by a number followed by a letter designation for the subfamily, and a second number that identifies the individual member of that subfamily.

- CYP1 drug metabolism (3 subfamilies, 3 genes, 1 pseudogene)
- CYP2 drug and steroid metabolism (13 subfamilies, 16 genes, 16 pseudogenes)
- CYP3 drug metabolism (1 subfamily, 4 genes, 2 pseudogenes)
- 5 CYP4 arachidonic acid or fatty acid metabolism (5 subfamilies, 11 genes, 10 pseudogenes)
- CYP5 Thromboxane A2 synthase (1 subfamily, 1 gene)
- CYP7A bile acid biosynthesis 7-alpha hydroxylase of steroid nucleus (1 subfamily member)
- CYP7B brain specific form of 7-alpha hydroxylase (1 subfamily member)
- 10 CYP8A prostacyclin synthase (1 subfamily member)
- CYP8B bile acid biosynthesis (1 subfamily member)
- CYP11 steroid biosynthesis (2 subfamilies, 3 genes)
- CYP17 steroid biosynthesis (1 subfamily, 1 gene) 17-alpha hydroxylase
- CYP19 steroid biosynthesis (1 subfamily, 1 gene) aromatase forms estrogen
- 15 CYP20 Unknown function (1 subfamily, 1 gene)
- CYP21 steroid biosynthesis (1 subfamily, 1 gene, 1 pseudogene)
- CYP24 vitamin D degradation (1 subfamily, 1 gene)
- CYP26A retinoic acid hydroxylase important in development (1 subfamily member)
- CYP26B probable retinoic acid hydroxylase (1 subfamily member)
- 20 CYP26C probable retinoic acid hydroxylase (1 subfamily member)
- CYP27A bile acid biosynthesis (1 subfamily member)
- CYP27B Vitamin D3 1-alpha hydroxylase activates vitamin D3 (1 subfamily member)
- CYP27C Unknown function (1 subfamily member)
- 25 CYP39 unknown function (1 subfamily member)
- CYP46 cholesterol 24-hydroxylase (1 subfamily member)
- CYP51 cholesterol biosynthesis (1 subfamily, 1 gene, 3 pseudogenes) lanosterol 14-alpha demethylase
- 30 The bulk of drugs are metabolised by a few members of the CYP1, 2, and 3 families and the metabolism occurs primarily in the liver, which contains the highest concentration of CYP450 in the body. However, the importance of extrahepatic metabolism in tissues such as the intestine and lung is also recognized.

The xenobiotic metabolizing P450s are approximately 50 kDa proteins anchored in the endoplasmic reticulum (ER) by a single transmembrane helix in the N-terminus. Cell fractionation using differential centrifugation results in particulate preparations enriched in endoplasmic reticulum, commonly referred to as microsomes. Detailed examination of microsomal fractions from many different individuals has demonstrated significant variability in expression patterns of individual isozymes, however some generalizations are possible (Guengerich, F.P. (1995) *Cytochrome P450: Structure, Mechanism, and Biochemistry* (Second Edition), Chapter 14, edited by Paul R. Ortiz de Montellano, Plenum Press, New York, Shimada, T., *et al.* (1994) *J. Pharmacol. Exp. Ther.* **270**:414-23). On average, 70% of the P450s expressed in adult human liver consist of the following isozymes: 1A2, 2A6, 2B6, the 2C subfamily (2C8, 2C9, 2C18, and 2C19), 2D6, 2E1, and the 3A subfamily (3A4 and 3A5).

Another very important aspect of the P450s is that polymorphisms cause significant differences in drug metabolism from population to population and *individuo* to *individuo*. A polymorphism is a difference in DNA sequence found at 1% or higher in a population. These differences in DNA sequence can lead to differences in drug metabolism, so they are important features of P450 genes in humans. CYP2C19 has a polymorphism that changes the enzyme's ability to metabolize mephenytoin (a marker drug). In Caucasians, the polymorphism for the poor metabolizer phenotype is only seen in 3% of the population. However, it is seen in 20% of the asian population. Because of this difference, it is important to be aware of a person's race when drugs are given that are metabolized differently by different populations. Some drugs that have a narrow range of effective dose before they become toxic might be overdosed in a poor metabolizer. A cytochrome P450 allele website is available from Sweden at <http://www.imm.ki.se/CYPalleles/>

Another aspect of the current invention is the ability to evolve drugs designed for specific populations or even individuals since the drug metabolic aspects can be addressed during the drug generation process.

Oxidation of organic molecules by P450s is quite complex (Ortiz de Montellano, P.R. (1995) *Cytochrome P450: Structure, Mechanism, and Biochemistry* (Second Edition), Chapter 8, edited by Paul R. Ortiz de Montellano, Plenum Press, New York), but the overall reaction can be represented simply by **Equation 1**:

An electron from NADPH is transferred via the flavin domain of NADPH-P450 reductase to the heme domain of the CYP450 where the activation of molecular oxygen occurs. Substrates react with one of the oxygen atoms and the other is reduced to water. In some cases, the second electron can come from NADPH via cytochrome *b5* reductase and cytochrome *b5*. During *in vitro* reconstitution experiments, cytochrome *b5* can stimulate metabolism of various substrates by some CYP450 isozymes, notably 3A4, 2E1, and 2C9. However, the mechanism of this stimulation is not clearly understood. Apocytochrome *b5* was shown to be as effective as the holoenzyme in stimulating reconstituted CYP3A4 reactions, so at least in this instance, it does not appear to be playing a direct role in electron transfer (Yamazaki, H., *et al.* (1996) *J. Biol. Chem.* **271**:27438-44). The most widely held hypothesis is that cytochrome *b5* acts allosterically to enhance the interaction between CYP450 and NADPH-P450 reductase, or it improves substrate binding.

Flavin Monooxygenases (FMOs)

Flavin monooxygenases, like the CYP450 enzymes, are associated with the endoplasmic reticulum and catalyze the oxidation of organic compounds using molecular oxygen and NADPH as the source of electrons for the reduction of one of the oxygen atoms (**Equation 1**). However, they are mechanistically distinct from the CYP450s in that they react with oxygen and NADPH in the absence of substrate to form a 4 α -hydroperoxy flavin enzyme intermediate. Thus, the FMOs exist in an activated form in the cell, and their interaction with a nucleophilic group such as an amine, thiol, or phosphate, is all that is required for completion of the catalytic cycle (Rettie, A.E. and Fisher, M.B. (1999) in *Handbook of Drug Metabolism*, pp131-147, edited by Thomas F. Woolf, Marcel Dekker, Inc, New York). The capacity to remain stable while poised in an activated state is a possible explanation for the extremely broad substrate specificity of the FMO isozymes. It has been proposed that essentially all of the energy required for catalysis is captured in the oxygen-activated intermediate, and that alignment or distortion of the substrate molecules is not required (Ziegler, D.M. (1993) *Annu. Rev. Pharmacol. Toxicol.* **33**:179). It follows that the active site of FMOs is much less sterically defined than for other enzymes. FMO3 is the most abundant form in human liver and is believed to be the dominant

member of this enzyme family in terms of overall drug metabolism (Rettie, A.E. and Fisher, M.B. (1999) in Handbook of Drug Metabolism, pp131-147, edited by Thomas F. Woolf, Marcel Dekker, Inc, New York).

5 *UDP glycosyltransferases (UGTs)*

UDP glycosyltransferases catalyze the glucuronidation of xenobiotics at hydroxyl, carboxyl, amino, imino, and sulphydryl groups using UDP-glucuronic acid as a donor molecule (**Equation 2**). In general, this generates products that are more hydrophilic and thus more readily excreted in bile or urine.

Equation 2: UDP-glucuronic acid + R → UDP + R-glucuronide

Although glucuronidation generally is classified as Phase II metabolism – the phase occurring after CYP450 dependent oxidative metabolism – many compounds do not require prior oxidation because they already possess functional groups that can be glucuronidated. Examples of first-pass metabolism catalyzed by UGTs include the UGT2B7- dependent glucuronidation of morphine (Coffman, B., *et al.* (1996) *Drug Metab. Dispos.* **25**:1-4) and the glucuronidation of 5-lipoxygenase inhibitors (anti-inflammatories) (Coffman, B., *et al.* (1997) *Drug Metab. Dispos.* **25**:1032-8); in the latter case, glucuronidation was demonstrated to be the rate-limiting step for *in vivo* plasma clearance. UGTs are 50-60 kDa integral membrane proteins with the major portion of the protein, including the catalytic domain, located in the lumen of the endoplasmic reticulum and a C-terminal anchoring region of 15-20 amino acids spanning the ER membrane (Radomska-Pandya, A., *et al.* (1999) *Drug Metab. Rev.* **31**:817-99.11. Radomska- Pandya, A., *et al.* (1999) *Drug Metab. Rev.* **31**:817-99). The aglycone-binding site is believed to be in the N-terminal portion the UGT polypeptide, which is the region of the protein that shows the greatest variability in sequence among UGT isozymes. The UDPGA binding domain is in the highly conserved C-terminal half of the protein. Although not a certainty, it has been hypothesized that association with lipid is required for UGT activity and may influence the access of aglycones to the active site. Two UGT families – UGT1 and UGT2 – have been identified in humans. Although members of these families are less than 50% identical in primary amino acid sequence, they exhibit significant overlap in substrate specificity (Radomska- Pandya, A., *et al.* (1999) *Drug Metab. Rev.* **31**:817-

99). The members of the UGT1 family that are expressed in human liver, where the majority of xenobiotic metabolism takes place, includes UGT1A1, 1A3, 1A4, 1A6, and 1A9. Although the UGT2 family has not been as extensively studied, it is known that UGT2B4, 2B7, 2B10, 2B11 and 2B15 are expressed in the liver (Radomska-Pandya, A., *et al.* (1999) *Drug Metab. Rev.* **31**:817-99.11. Radomska-Pandya, A., *et al.* (1999) *Drug Metab. Rev.* **31**:817-99). As is the case for other drug metabolizing enzymes such as CYP450s, inter-individual differences in UGT expression levels have been observed and linked to differences in drug responses (Weber, W. (1997) *Pharmacogenetics*, Oxford University Press, New York).

The human UGT1 family includes the major bilirubin metabolizing isoform (UGT1A1) and the isoform that preferentially conjugates planar phenols (UGT1A6). Isoforms in the UGT2 family metabolize a variety of endogenous steroid compounds, as well as xenobiotics. As with the CYP450s, classification of the UGTs based on substrate specificity is somewhat limited since there is a great deal of overlap in the biotransformation capacity for most of the human UGTs.

Glutathione transferases (GSTs)

Glutathione transferases catalyze the formation of thioether conjugates between glutathione (GSH) and reactive xenobiotics by direct addition (**Equation 3**) or displacement of an electron-withdrawing group (**Equation 4**).

Equation 3: $\text{GSH} + \text{R} \rightarrow \text{GS-R}$

Equation 4: $\text{GSH} + \text{R-X} \rightarrow \text{GS-R} + \text{HX}$

The major biological function of GSTs is believed to provide defense against electrophilic chemical species. The majority of GSTs are cytosolic homodimers composed of approximately 25 kDa subunits from one of four structural classes: Alpha (α), Mu (μ), Pi (π), and Theta (θ). The α isoform (GST A1-1) is restricted to a few tissues in mammals, including kidney, intestine, lung and liver. The μ isoform (GST M1-1) is found in the liver, but relatively few other tissues. In contrast, the π isoform (GST P1-1) is widely distributed throughout the body, although it is notably absent in the liver. Additionally, GST P1-1 is abundant in most types of tumor cells.

Sulfotransferases (SULTs)

Sulfotransferase enzymes catalyze the conjugation of sulfate groups onto a variety of xenobiotic and endogenous substrates that possess acceptor moieties such as hydroxyl and amine groups (**Equation 5**).

The cofactor 3'-phosphoadenosine 5'-phosphosulfate (PAPS) is required for sulfonation by these enzymes. Although sulfonation generally causes molecules to lose their biological activity, several documented examples indicate that the addition of sulfate can lead to formation of highly reactive metabolic intermediates, such as minoxidil, and reactive electrophilic cations, such as sulfated N-hydroxy 2-acetylaminofluorene (McCall, J., *et al.* (1983) *J. Med. Chem.* **26**:1791-3; Miller, J.A. (1994) *Chem. Bio. Interact.* **92**:329-41). Several sulfotransferase enzymes with different biochemical properties have been characterized in animal and human tissue. Two general classes exist in tissue fractions: the cytosolic enzymes, which are considered important in drug metabolism; and the membrane bound enzymes, which are involved in the sulfonation of glycosaminoglycans and glycoproteins (Weinshilboum, R.M., *et al.* (1997) *FASEB J.* **11**:3-14). The human cytosolic sulfotransferase isozymes function as homodimers of 32-35 kDa subunits. There are currently 10 known sulfotransferases in humans, five of which are known to be expressed in adult liver (SULT1A1, SULT1A2, SULT1A3, SULT1E and SULT2A1). It is expected that other new genes encoding sulfotransferases will be identified. The nomenclature of the different genes, their mRNA and protein products has recently been revised so that "SULT" is the accepted superfamily abbreviation (Raftogianis, R.B., *et al.* (1997) *BBRC* **239**:298- 304). Allelic variants of sulfotransferase enzymes do exist and studying their frequency and functional role in drug disposition is a very active area of research.

N-acetyl Transferases

N-acetyltransferases (NATs) catalyze the biotransformation of aromatic amines or hydrazines to the respective amides and hydrazides (**Equation 6**) using acetyl co-

enzyme A as a donor. They also will catalyze the O-acetylation of N-hydroxyaromatic amines to acetoxy esters (**Equation 7**).

Equation 6: $R-NH_2 + CoA-S-COCH_3 \rightarrow R-NCOCH_3 + CoA-SH$

5 **Equation 7: $R-NHOH + CoA-S-COCH_3 \rightarrow R-NHOCOCH_3 + CoA-SH$**

There are two known NAT isoforms in humans called NAT1 and NAT2; both are 33 kDa cytosolic proteins found in the liver. NAT1 is also expressed in many other tissues, whereas NAT2 is expressed only in the liver and gut. The two isoforms have
10 different, but overlapping substrate specificities, with no single substrate appearing to be exclusively acetylated by one isoform or the other. Genetic polymorphisms for N-acetylation are well documented, and may play a role in the susceptibility of certain individuals to bladder and colon cancer, as the NATs are involved in both the activation and detoxification of heterocyclic aromatic amine carcinogens (Weber, W.
15 (1997) Pharmacogenetics, Oxford University Press, New York).

Toxicity

One of the main forms of toxicity is hepatotoxicity. Freshly isolated human hepatocytes represent the best in vitro biological system in which to evaluate toxicity. Some
20 human liver cell lines have been developed that reflect normal human liver metabolism (e.g., ACTIVTox from Amphioxus Inc, and Hep G2 from Cerep). These cell lines can be used in cell proliferation assays that give very good correlation with in vivo results.

25 In the present invention toxicity assessment is an inherent parameter of the screens since the compounds are produced in a host organism. Any compound that is very toxic will not be selected or detected since it will kill the host organism. Broadly speaking, toxicity can be screened for using a cell proliferation assay. A more accurate human toxicity assay can be incorporated in the multiple parameter screening
30 procedure by for example encapsulating hepatocytes with the producer species and disease target(s) and select screening units that activated the disease target(s) in the desired way and have not inhibit hepatocyte growth.

35 Figure 7 shows a schematic representation of a screening system of the present invention to evaluate target activity, metabolism by DMEs and cytotoxicity: Using a

double gel encapsulation system where in the first droplet are clonal lines of the producer species transformed with the pharmacological target and DMEs, and in the second droplet are hepatocytes, it is possible to screen for target activity, DME metabolism and hepatotoxicity.

5

Mutagenicity

The mutagenic ability of a compound is another aspect that has to be addressed in a drug discovery programme. The mutagenicity of a compound can be evaluated by measuring the reverse-mutation rate in an organism. The organism can be animals or more preferably microorganisms. For example, there are several different strains with differing and complementary sensitivities to potential mutagens of the bacterium *Salmonella typhimurium*.

10

MULTIPLE PARAMETER SCREENING FOR OTHER PURPOSES

15

Screening for herbicides.

The effect of a compound as a herbicide can be screened with in vitro assays. Primary screens that test the effect as a herbicide include: toxicity, inhibition of photosynthesis, inhibition of central metabolic enzymes.

20

Examples of further screens that can be assayed simultaneously with the first group include: uptake (using hairy root cultures, organ cultures (including shoot cultures), metabolism, lack of toxicity towards other plants (in particular crops) or towards other organisms (animals, humans, insects, fungi).

25

Screening for fungicides (agricultural)

Primary screens are much like the ones used in screening for or evolving herbicides except that fungal cells are used as reporter cells and for uptake.

30

Secondary screens are also more or less of the same type. One particular screen to perform is lack of toxicity towards plants, in particular crop plants.

35

Screening for insecticides

5 Primary screens include the assays for the function of the compounds as insecticides, i.e. cell based assay for toxicity towards a specific species or group of species of insects, and/or assays for inhibition of specific enzymes in key metabolic functions of insects, or inhibition of reproduction.

10 Secondary screens may include uptake in specific insect organs using e.g. a confluent monolayer of insect cells from the organ in which the insecticide is to be taken up. A further screen includes metabolism by insect metabolic enzymes to test whether the compounds are metabolised or activated by these. Furthermore, it is relevant to screen for lack of toxicity or mutagenicity or teratogenicity towards animals and/or human beings. Another example of a secondary screen is lack of toxicity towards other species of insects.

15

Screening for cosmetics

Primary screens are directed to the function of the compounds as cosmetics.

20 Secondary screens include the same as for screening for or evolution of pharmaceuticals, i.e. absorption (if relevant), distribution (if relevant), metabolism, excretion (if relevant) and toxicity, mutagenicity and teratogenicity.

Screening for flavours

25

Primary screens may include automatic assaying for the desired flavour. "Artificial noses" have been developed that can assay for particular flavours or tastes. Artificial noses, or olfactory or vapor-selective detectors can detect low levels of odorants. Examples of such noses are disclosed in e.g. US 6,368,558 and references cited therein. The technique is also known as artificial olfactometry.

30

Secondary screens typically include toxicity, mutagenicity, teratogenicity, metabolism (by e.g. saliva enzymes).

Fine chemicals: other examples of multiple parameter screening and evolution include the evolution and screening for fine chemicals, food and feed additives, and catalysts.

5 SCREENING TECHNIQUES

The selection of the positive cells can be achieved by establishing screens where only positive cells survive or by physically selecting positive cells. Survival of positive clones can e.g. be achieved by using assays based on

- 10 a. Survival in the presence of toxic substances
- b. Survival in the presence of other organisms
- c. Use of nutritional reporter genes, e.g., His, or of reporter genes that when giving desired response produce a vital protein, e.g., CDC25
- 15 Physical selection of positive cells can be done by the use of:
 - a. FACS & intracellular reporter assays (native or engineered)
 - b. FACS & gel encapsulation (single, double or more) & extracellular reporter systems [cell based (native or engineered) or cell free]
 - c. Overlay assay & extracellular reporter systems [cell based (native or
 - 20 engineered) or cell free] & picking (manual or automatic)
 - d. Single clonal cell line confinement to microtiter plate & extracellular reporter systems [cell based (native or engineered) or cell free] & picking (manual or automatic)
 - e. Plating & picking (manual or automatic)

25

Flow cytometry

In traditional flow cytometry, it is common to analyze very large numbers of cells in a short period of time. Newly developed flow cytometers can analyze and sort up to

30 100,000 cells per second. In a typical flow cytometer, individual particles pass through an illumination zone and appropriate detectors, gated electronically, measure the magnitude of a pulse representing the extent of light scattered. The magnitude of these pulses are sorted electronically into "bins" or "channels", permitting the display of histograms of the number of cells possessing a certain

35 quantitative property versus the channel number. It was recognized early on that the

data accruing from flow cytometric measurements could be analyzed (electronically) rapidly enough that electronic cell-sorting procedures could be used to sort cells with desired properties into separate "buckets", a procedure usually known as fluorescence-activated cell sorting (FACS).

5

Fluorescence-activated cell sorting has been primarily used in studies of human and animal cell lines and the control of cell culture processes. Fluorophore labeling of cells and measurement of the fluorescence can give quantitative data about specific target molecules or subcellular components and their distribution in the cell population. Flow cytometry can quantitate virtually any cell-associated property or cell organelle for which there is a fluorescent probe (or natural fluorescence).

10

Cell sorters can handle cell sorting at rates of at least 10,000 cells per second, more preferably at least 50,000 per second, more preferably at least 100,000 per second.

15

Gel microdroplet encapsulation

The gel microdroplet technology has had significance in amplifying the signals available in flow cytometric analysis, and in permitting the screening of microbial strains in strain improvement programs for biotechnology. Wittrup et al., (Biotechnol. Bioeng. (1993) 42:351-356) developed a microencapsulation selection method which allows the rapid and quantitative screening of $>10^6$ yeast cells for enhanced secretion of *Aspergillus awamori* glucoamylase. The method provides a 400-fold single-pass enrichment for high-secretion mutants.

25

Gel microdroplet or other related technologies can be used in the present invention to localize as well as amplify signals in the high throughput screening of cells. Preferably the screening methods of the present invention are laid out to ensure survival of the producer cell, so that these can be used for further rounds of evolution. However, it is also possible to isolate the expression cassettes and possibly even the artificial chromosomes from the cells and re-insert these into other host cells should this be necessary if the cells are killed by the screen.

30

Different types of encapsulation strategies and compounds or polymers can be used with the present invention. An encapsulation of particular relevance is the

35

encapsulation in calcium alginate due to its broad applicability. Furthermore, calcium alginate beads can be made at room temperature and be dissolved by gentle procedures leaving the encapsulated cells alive.

- 5 A further feature of particular interest is the possibility of coating the beads (or gel microdroplets) with a lipid layer in order to make them impermeable to small molecules. This ensures that small molecules do not leak to the surroundings and that the connection between producer cell and small molecule is not lost during screening and sorting of gel microdroplets.

10

Encapsulation techniques may be employed to localize signal, even in cases where cells are no longer viable.

15

Gel microdrops (GMDs) are small (25 to 200 μm in diameter) particles made with a biocompatible matrix. In cases of viable cells, these microdrops serve as miniaturized petri dishes because cell progeny are retained next to each other, allowing isolation of cells based on clonal growth. The basic method has a significant degree of automation and high throughput. Cells are encapsulated together with substrates and particles containing a positive clones are sorted.

20

Fluorescent substrate labeled glass beads can also be loaded inside the GMDs. In cases of non-viable cells, GMDs can be employed to ensure localization of signal.

25

Encapsulation can be in beads, low or high temperature agaroses, gel microdroplets made from agarose, polysaccharide, carbohydrate, alginate, carrageenan, chitosan, cellulose, pectin, dextran, or polyacrylamide, cells, such as ghost red blood cells or macrophages, liposomes, or any other means of encapsulating and localizing molecules.

30

Gel encapsulated cells may further be enclosed in a layer essentially non-penetrable by the compounds being screened. Thereby it is ensured that the compounds remain within the vicinity of the cell and that the physical connection between cell and compound is not lost. Furthermore leakage from gel droplet to gel droplet is prevented. The non-penetrable material may be a lipid material.

The cells and the reporter system(s) may be encapsulated into one layer of gel droplets. The cell may also be encapsulated in one layer of the gel droplet and at least one reporter system is encapsulated in another layer of the same gel droplet. In another embodiment, one layer comprises the cells and one or more reporter system(s), and a second layer comprises one or more different reporter system(s), and optionally a third or fourth or further layer comprises one or more reporter system(s). Furthermore, the cell may be encapsulated in one layer of the gel droplet and a first reporter system is encapsulated in another layer of the same gel droplet and at least a second reporter system is encapsulated into yet another layer of the same gel droplet.

For example, methods of preparing liposomes have been described (i.e., U.S. Pat. Nos. 5,653,996, 5,393,530 and 5,651,981), as well as the use of liposomes to encapsulate a variety of molecules U.S. Pat. Nos. 5,595,756, 5,605,703, 5,627,159, 5,652,225, 5,567,433, 4,235,871, 5,227,170). Entrapment of proteins, viruses, bacteria and DNA in erythrocytes during endocytosis has been described, as well (Journal of Applied Biochemistry 4, 418-435 (1982)). Erythrocytes employed as carriers in vitro or in vivo for substances entrapped during hypo-osmotic lysis or dielectric breakdown of the membrane have also been described (reviewed in Ihler, G. M. (1983) J. Pharm. Ther). These techniques are useful in the present invention to encapsulate samples for screening.

An environment suitable for facilitating molecular interactions include, for example, liposomes. Liposomes can be prepared from a variety of lipids including phospholipids, glycolipids, steroids, long-chain alkyl esters; e.g., alkyl phosphates, fatty acid esters; e.g., lecithin, fatty amines and the like. A mixture of fatty material may be employed such as combination of neutral steroid, a charge amphiphile and a phospholipid. Illustrative examples of phospholipids include lecithin, sphingomyelin and dipalmitoylphosphatidylcholine. Representative steroids include cholesterol, cholestanol and lanosterol. Representative charged amphiphilic compounds generally contain from 12-30 carbon atoms. Mono- or dialkyl phosphate esters, or alkyl amines; e.g., dicetyl phosphate, stearyl amine, hexadecyl amine, dilauryl phosphate, and the like.

Other screening systems

As an alternative to gel droplet screening the selection of positive cells meeting the at least one selection criterion may be performed by means of an overlay assay, said overlay assay comprising reporter system(s), and manual or automatic picking of positive cells.

Other systems for screening include the selection of positive cells meeting the at least one selection criterion and is performed by means of placing a single clonal cell line in one well of a microtiterplate, said well comprising reporter system(s), and manual or automatic picking of positive cells. This system takes advantage of the many systems developed for automatic handling and analysis of microtiterplates.

Cells may also simply be plated on medium and positive cells can be picked either automatically or manually.

Cells may also be engineered so that only positive cells are able to survive. These cells may be grown in liquid media or be plated.

Evolution towards multiple parameters

Evolution at its most general is a process, whereby a set of replicating and varying patterns are subjected to a selection process that favours the replication of certain of the variant patterns. The selection process acts on an emergent property (phenotype) that is encoded by the pattern and that varies as a consequence of the underlying variation in the pattern. Over the course of a series of replication events those patterns whose replication is most favoured come to dominate the population.

Variation in the patterns occurs as the result of changes in individual patterns or as the result of mixing of individual patterns. Which patterns come to dominate the population is partly a consequence of the selection criteria used and partly a function of the starting population.

In living organisms and cells the predominant replicating pattern consists of nucleotide sequences (DNA or – in some virus – RNA) and the criteria on which

selection acts it typically mediated through other molecules such as (but not limited to) proteins, metabolites, and structural macromolecules that are encoded by the nucleotide sequence either directly or indirectly.

5 In genetic algorithms the replicating pattern consists of software defined magnetic states and the variation on which selection acts is typically (but not limited to) the solution of a mathematical algorithm encoded by the magnetic states either directly or indirectly.

10 The ability of a pattern to replicate in a given set of environmental parameters is often referred to as the "fitness" of the pattern. Fitness can be regarded as a mathematical property that replicating patterns "attempt to" optimise. The higher the fitness of any given pattern, the greater the chance it will produce one or more copies of itself, the higher the number of copies it will on average produce, and the
15 lower the chance it will be destroyed prior to replication. As with any mathematical function the property that is optimised may itself be a complex function of otherwise independent properties. Thus evolution can optimise across more than one criteria. For instance the mating calls of many male insects are optimised to attract females of the same species whilst not attracting predators.

20 Cells containing genetic material are thus in principle able to evolve by virtue of the variations in the genetic sequence that occur within each cell and the consequences of this variation upon the fitness of the cell in a given set of environmental parameters and the ability of the cell to pass these genetic sequences on to
25 descendant cells

For the purposes of this invention the term "Fitness Function" shall be taken to mean a mathematical or algebraic equation that calculates a score and where the variable elements in the equation are output variables that vary between different cells within
30 a *cell population*.

For the purposes of this invention the term "Fitness Score" shall be the score generated by the *fitness function* equation.

It shall be understood that any selection process conducted on cells may therefore be conducted according to the following general procedure:

- The fitness function (F') is defined so that it comprises the desired phenotype of the cell and mathematically relates this to measurable parameters
- Each cell or group of cells is measured on one or more parameters
- F' for the cell is calculated according to the measured parameters
- Those cells with the highest F' scores are removed from the screening locality and allowed to grow. Cells with lower F' scores are discarded. By the highest F' score is meant a predetermined percentage of the cells with the highest score, such as the best 1%, 5%, 10 % or 50%, or for very high selection pressures the best 1‰, the best 0.1 ‰, the best 0.01 ‰, the best 0.001 ‰, or the best 0.0001‰.

It is an important teaching of evolution that the criteria on which certain patterns are selected over other patterns is essentially arbitrary – in principle any criterion can be used. That arbitrary, human imposed criteria can be used to generate an evolutionary process in a whole organism is exemplified by the evolution of melanism in moths as a result of industrialisation, the evolution of pedigree dogs with various properties and the evolution of plants with e.g. enhanced levels of commercially valuable oils or more even fruiting times or more attractive scents and colours. The term “breeding” is often used to describe human imposed evolution. Such organisms have increased their fitness according to a given set of human imposed criteria. It shall be obvious from these examples that it is not necessary for the fitness function equation to be explicitly described for the evolution to take place.

It is a further teaching that fitness functions and consequent selection pressures can lead to the organism expressing phenotypes that impose high costs on (and even in some cases kill) the organism. All that is required for this to be the case is that they confer a countervailing benefit that allows the underlying pattern that produces the phenotype to spread. One example is the evolution of the peacock's tail, which whilst making it highly visible and vulnerable to competitors and predators, improves its ability to attract mates and hence replicate. In organisms with diploid or higher ploidy and with sexual reproduction it is even possible for patterns that have a net cost to be maintained in the population at reasonable levels. One example of this is

the maintenance of the sickle cell anaemia mutation in west african human populations. The heterozygote form of the mutation confers a benefit (by making the carrier more resistant to malaria) whilst the homozygote is costly (causing severe anaemia). The positive benefit of the heterozygote results in the underlying pattern being maintained in the population at a relatively high frequency.

It is a further teaching that multiple selection pressures, acting on a population at different locations and times help develop and maintain the variability of replicating patterns in the population.

It is a further teaching that if two identical selection pressures are applied to two independent but apparently identical populations then although such populations will each evolve similar phenotypes the genetic patterns that come to dominate the population (and that confer the evolved phenotype) may differ between the populations. An example of different genetic patterns conferring the same phenotype is streptomycin resistance in bacteria.

From the above it should be clear that organisms are capable of complex evolutionary responses to a wide range of environmental pressures.

The evolution according to the present invention is based on a series or cycle of steps of subjecting a composition of cells to screening and selecting cells exhibiting a predetermined functionality, as shown in Fig. 21. The cycles are repeated until the desired functionality, for example a target specificity and activity is obtained. Another example of general screening strategies is illustrated in Figure 22.

In other words, the method of evolution according to the present invention is based on the provision of

1. a suitable set of diverse genetic patterns and also
2. a way of selecting for those genetic patterns within this set that encode for phenotypes that are consistent with these properties and also
3. a way of generating novel genetic patterns from those patterns that were selected in step 2.

These steps may then be combined sequentially or in parallel or in some other essentially iterative basis. The present invention lays out how to achieve these requirements.

5 In another aspect of the invention, the methods may be applied to the generation of a pathway derived from sources from multiple natural kingdoms, phyla or orders in the host cell. An example of this would be the generation of a pathway to produce retinoids or other molecules by means of introduction of genes encoding for the production of carotenoid pathways (obtained from fungi, algae and/or plants) as well
10 as genes encoding for the synthesis of Vitamin A (obtained from mammals) or genes encoding for the production of visual pigments (obtained from insects). By such targeted selection and combination of elements of biochemical pathways across kingdoms or phyla the likelihood of obtaining novel metabolites may be further increased.

15 As previously described a fitness function (F') can be defined that encapsulates the desired phenotype of the cell and mathematically relates this to one or more measured outputs. For example the fitness function may be defined as the multiplum of a cell's absorption at two different wavelengths or alternatively it may
20 be defined as the level of inhibition of one enzyme, divided by the inhibition of another enzyme, or it may be defined as the level of cytotoxic poison that a cell can survive, multiplied by the rate or reproduction of the cell in the absence of the cytotoxin or it may be defined in numerous other ways

25 In each screening round cells are selected that have outputs that correspond to one or more elements of the fitness function. In a preferred embodiment early screening rounds only measure one output whilst later screening rounds measure multiple outputs.

30 Those cells with the highest *fitness scores* in the population are removed from the screening environment for later use and/or analysis. Cells with lower F' scores may be discarded. By the highest F' score can be meant a predetermined percentage with the highest score, such as the best 1%, 5%, 10 % or 50%, or for very intense selection or very large cell populations the best 1‰, the best 0.1 ‰, the best 0.01
35 ‰, the best 0.001 ‰, or the best 0.0001%. Alternatively an absolute fitness score

can be defined and only those cells that exceed this score are selected. By this approach the percentage of cells that are selected may vary.

5 In a preferred embodiment of this invention the screening and selection processes should be conducted on a repetitive or iterative basis, with each iteration being conducted on a daughter population.

10 For each iteration of the screening step, the fitness score that the cells are categorised upon is defined and the cell population subjected to screening. Over a series of iterations the fitness score is elaborated such that it progressively approaches the desired target value. The fitness score may be elaborated either by being increased or by having additional factors added into the equation that derives the fitness score.

15 The selection criteria are hence progressively optimised towards the desired functionality through the necessary rounds or cycles of screening and selection. The steps are repeated until at least one cell having the desired functionality has been evolved, such as repeated at least twice, such as at least three times, such as at least four times, such as at least five times, such as at least ten times, such as at
20 least twenty times, such as least fifty times, such as at least one hundred times, such as at least two hundred times

In another embodiment the steps are repeated until at least two cell lines, or at least five cell lines, or at least 10 cell lines, having the desired functionality have been
25 evolved. In a preferred embodiment at least a part of the cell lines evolved have different genetic patterns or genotypes, in a more preferred embodiment all the cell lines evolved have different genetic patterns or genotypes. By the term cell lines is meant cells originating from cells having met the selection criteria related to the determined screening functionality.

30 The selection criteria (or threshold) for one or more outputs may be increased for each repetition. Increasing criteria may for example be increasing concentration of a chemical, such as a toxin, in growth media for each repeat, or decreasing concentration of one or more nutrition components in the growth media or
35 decreasing sensitivity or proximity of a reporter construct. Other examples of

increasing criteria may be repetitive changes of temperature, either increasing or decreasing depending on the cell type chosen.

5 The selection criteria may also change character per repeat, such as starting with a concentration of a chemical substance in the growth media, and adding a physical parameter, such as light, in the next repeat, or starting with measuring the activity against one enzyme and adding activity against another enzyme in the next repeat.

10 It is also within the scope of the present invention that selection criteria may be a mixture of the criteria discussed above, ie. increased concentration of a chemical combined with changes of physical parameters, and/or increased concentration of one chemical combined with changed concentration of another.

15 Through this approach and in accordance with the general principles of evolution, over a series of screening and selection cycles host lines that most demonstrate the required characteristics are selected for and come to dominate the population. Over a series of screens the required fitness score is raised or elaborated, favouring those combinations that have led to an improvement in the expression of the desired characteristics.

20 In one embodiment the host cell lines that are a priori believed to be interesting for a given target are selected and the selected lines evolved through a series of screens as set out in Figure 21.

25 In another embodiment the approach is one of an escalator of selection pressure using screens that move from the general / low activity to the specific / high activity with the generation of new genetic patterns between each step.

30 In another embodiment the fitness score is deliberately raised only marginally between selection cycles, such as by no more than 50% or by no more than 25% or by no more than 10% or by no more than 5% or by no more than 1%. Such gradualist selection pressures allow low level responses to be built upon over a series of selection cycles. By selecting marginal improvements in the fitness score such an approach maximises the genetic diversity at each stage in the selection
35 process.

Generation of Novel Genetic Compositions

5 It is a requirement of evolutionary processes that new patterns are generated either in parallel to or sequential to selection steps. In systems where the patterns are based on genetic elements this requires that either new genetic elements are introduced or new combinations of existing genetic elements are created or both.

10 In the present invention new patterns can be achieved through one or more of the following processes. The term combining or remixing shall be taken to mean a process of generating new combinations of expression constructs using one or more of these approaches. The combination or remixing may be conducted at any step of the selection process and a preferred timing is when cells having elements of the predetermined functionality have been found in at least one of the compositions, and
15 preferably in at least 0.1%, such as at least 1%, such as at least 2%, such as at least 5%, such as at least 10% or at least 50% of compositions. The term Daughter Population shall be taken to mean a cell population that is predominately genetically descendant from those cells in one or more cell populations that had a fitness score above a certain threshold and that is further characterised by most of the cells in the
20 daughter population having been generated through a remixing step.

In principle the combination or remixing may be conducted by at least the following approaches: physical isolation and remixing of expression cassettes, physical isolation and remixing of artificial chromosomes containing expression cassettes,
25 sexual crosses, cell- or protoplast fusion (vide Hugerat Y, Spencer F, Zenwirth D, Simchen G (1994). Genomics 22(1), p. 108-117), and YAC-duction (vide Curran BP, Bugeja VC (1996), Methods Mol. Biol. 53, p 45-49. One example of physical remixing is illustrated in Figure 23.

30 One advantage of physical isolation is that any accumulating host mutations are removed by the remixing of genes into new host lines. Reporter genes can also be introduced as part of this process, allowing for the introduction of intracellular reporter assays. The remixing is preferably carried out in vitro by isolating the expressible sequences from at least two different cells, combining the individual
35 expressible sequences in vitro into novel combinations, and introducing the

combined expressible sequences into cells to obtain at least two cells with different combinations.

Due to the common structure of the expression cassettes according to a preferred embodiment of the invention (see the section starting page 98 "Concatamers"), these may easily be excised from the host cells again using a restriction enzyme specific for the rs_1 - rs_2 restriction site. According to the present invention the enzyme specific for the rs_1 - rs_2 restriction site is preferably a rare cutter therefore the likelihood of cutting host genomic DNA fragments with a size similar to the size of the expression cassettes is very limited. After excision the expression cassettes may be mixed with other expression cassettes of similar structure and be re-concatenated to produce novel combinations and re-inserted into another host cell in another combination creating a greater diversity during the evolution steps.

The combination of expressible sequences may of course also be a combination of full length chromosomes in the cells, such as combination of artificial chromosomes. Combination of the artificial chromosomes may be achieved in at least 4 ways depending on the host cells. These are physical isolation, crosses, protoplast fusion and YAC-duction as described herein.

An alternative way of physically remixing expression cassettes is to isolate the artificial chromosomes from one or more cell populations and re-transform new host cells. The host cells may or may not already contain artificial chromosomes containing expression cassettes.

Thus, new genetic compositions may be achieved by induction of different mating types in the two (or more) populations followed by sexual crosses yielding cells that are diploid for the normal complement of chromosomes and contains the artificial chromosomes of both partners in the cross.

Addition of new genetic material.

The remixing is preferably conducted with addition of new genetic material from another cell composition. The other composition may be chosen from compositions capable of expressing at least one predetermined phenotype, such as a protein or a

metabolite, a given metabolic pathway or part thereof or it may be chosen at random.

5 In one embodiment it is desirable to conduct selection in a series of isolated populations that are then brought together once they have independently evolved useful traits. In this manner the use of independent selections for same phenotype provides different genetic backgrounds (a form of parallel evolution) that can then ideally act synergistically with each other.

10 In another embodiment the result of selection on two or more compositions is mixed at a certain step of evolution to create further modified compositions when aiming for at least one cell having the desired functionality.

15 Recombination of the expressible sequences, i.e. changes of the genetic material by for example cross-over, may be optionally avoided, through the construction of the genetic inserts, in particular spacer sequences, as well as due to a general attempt to suppress recombination in the cells. Thereby combination of intact genes or cDNA material is favoured, with lesser risk of destroying the function of the genetic material due to recombination.

20 Having obtained daughter populations exhibiting the desired functionality, the daughter population may then be subjected to further steps of screening and selection in order to optimise the cells.

25 **Evolved Cells**

In another aspect the invention relates to the cells evolved having the desired functionality. In a preferred embodiment the cells evolved have a genetic construction as defined above in relation to the starting material, however often
30 having another combination of heterologous genetic material than the starting population.

The evolved cells may be subjected to analysis with respect to the gene(s) responsible for the desired functionality in order to possibly optimise the genes
35 leading to the desired phenotype.

However, the cells may also be used as such as production cells capable of producing a novel metabolite or a novel pathway. In this respect it is preferred that the cells evolved are cells suitable for production in for example fermentation tanks.

5

Novel Molecules and Pathways

The aim of the evolution method according to the present invention is to evolve cells capable of producing new substances, such as new metabolites, new proteins, and/or having new pathways.

10

Thus, in a further aspect the present invention relates to a substance produced by the cells evolved according to the present invention, said substance being metabolites, proteins, carbohydrates, poly- and oligosaccharides, and nucleic acids.

15

Since some of the interactions that produce the novel phenotypes are mediated by enzymes it is likely that the result will include novel compounds with chiral centres, which are especially difficult to produce via chemical synthesis.

Creation of novel pathways, may lead to the capability of creating cells capable of metabolising, i.e. converting, a compound, which is not metabolisable by the native, un-evolved cell.

20

Specific strategies for pathway generation

In another embodiment the approach is to walk down a specific multi-step metabolite pathway in a manner analogous to playing a slot machine. Once the first step of the pathway is obtained the genetic material for that step is put on "hold" by increasing its relative abundance such that most cells in the cell population contain said genetic material and the other genetic materials are then varied (spun or permed) until the second step is achieved, which is then also put on "hold". This process is repeated until the entire pathway is obtained.

30

In another embodiment the approach is to go backward in the construction of a specific multi-step pathway. Once the last step of the pathway is obtained the genetic material for that step is put on "hold" by increasing its relative abundance

35

such that most cells in the cell population contain said genetic material and the other genetic materials are then varied (spun or permed) until the next but last step is achieved, which is then also put on "hold". This process is repeated until the entire pathway is obtained.

5

Also, a combination of both embodiments may be conducted, so that the pathway is built up from "both ends".

10

In one embodiment of the invention the cells are subjected to the selection criteria under conditions that maximise the number of genes expressed by the cells, including the genes being heterologous to the cells. Alternatively the cells are subjected to the selection criteria under conditions that ensure that only a certain percentage of or a subset of the genes being heterologous to the cells are expressed

15

It should be understood that the above approaches are general in concept and lend themselves to the construction of many variants, depending on the desired goal.

20

Furthermore, it should be understood that by using a cell-based system an advantage is that the compounds may be selected also on parameters not being included in the fitness function, in that the system inherently promotes evolution of compounds exhibiting properties such as not being toxic to the cell, as well as compounds that diffuse rapidly within the cell.

25

Examples of the approaches to build known or structural class focused pathways are as follows:

30

For small to medium sized pathways, i.e. pathways of up to 6-7 steps from metabolites of the host cell, the screening strategy relies on enriching the founder population with relevant genes and on the reasonably high probability of assembling over a series of selection rounds pathways that produce a low level of the desired property.

For large pathways (i.e. more than 6-7 steps) the screening strategy may involve dividing the pathway into subsets and a) defining screening parameters for each

subset in order to build a pathway forwards or b) identifying intermediate metabolites that are fed to the cell population in order to assemble the pathway backwards.

For example in the case of retinoid like compounds it is well known that carotenoids are metabolised by specific tissues in specific classes of organisms to produce retinoids. It is thus possible to first evolve a population of cells that produce carotenoids and then mix the genes of this population(s) with those of a population(s) enriched for retinoid genes and in this manner evolve a population that produce retinoid like compounds.

Another example is the case of Taxol like compounds, for which the exact biosynthetic pathway is not known but is predicted to be somewhere between 12 and 20 enzymatic steps from yeast metabolites and several of the intermediate compounds have been isolated. It is thus possible to start by feeding a metabolite that is a few steps from Taxol in order to identify a population of cells able to produce Taxol like compounds from this precursor. Once this is achieved, the genes responsible for that small pathway are locked, e.g., integrated in the host's genome, or incorporated in artificial chromosomes at such high levels that statistically they occur in most cells and a second evolution process is started. This time the precursor being fed to the cell population is an earlier metabolite from the Taxol biosynthesis. By repeating these partial evolutions a number of times, it is possible to evolve a population of cells that produce Taxol like compounds starting with host metabolites.

Finally it should be said it is also possible to produce a class of compounds using a combination of both approaches described, i.e., by starting simultaneous evolution processes that cover the pathway backwards and forwards.

Diverse Genetic Patterns

Given that evolution is a statistical process it is necessary to provide sufficient genetic variation on which selection processes can act. In the present invention, this comprises two elements

- Providing a sufficiently large and diverse population
- Controlling the genetic basis of the diversity and how it expresses

Selection requires genetic diversity on which to operate. Thus the first requirement of the current invention is to provide a population of cells that embodies a genetic diversity. The term "*genetic diversity*" means that substantially all cells are different, in that they comprise different genes, and/or identical genes under control of different control system, such as different promoters, such that almost each cell initially represents a genotype not represented in any of the other cells. Of course due to cell division a few cells may be substantially identical.

The term "Cell Population" shall be taken to mean a population of cells where at least 10^4 cells, such as at least 10^5 cells, such as at least 10^6 cells, such as at least 10^7 cells, such as at least 10^8 cells, such as at least 10^9 cells, such as at least 10^{10} cells, such as at least 10^{11} cells, such as at least 10^{12} cells, such as at least 10^{13} , such as at least 10^{14} , such as at least 10^{16} , for example at least 10^{18} , such as at least 10^{20} in the population represent a genotype not represented in any of the other cells.

Thus, the principle of the evolution method according to the invention is to obtain a population of cells having a very high genetic diversity.

One particular embodiment of this principle is to produce cells with combinations of concatemers comprising cassettes with expressible nucleotide sequences from a number of different expression states, which may be from any number of unrelated or distantly or closely related species, or from species from different kingdoms or phylae such that novel and random combinations of gene products are produced in one single cell.

By inserting novel genes into the host cell, and especially by inserting a high number of novel genes from different expression states, such as from a wide variety of species into a host cell, the gene products from this array of novel genes will interact with the pool of metabolites of the host cell and with each other and modify known metabolites and/or intermediates in novel ways to create novel compounds. Due to the high number of substantially different cells that can be generated using the methods according to the present invention, for example at least 10^4 cells, such as at least 10^5 cells, such as at least 10^6 cells, such as at least 10^7 cells, such as at least 10^8 , such as at least 10^9 , for example at least 10^{10} , such as at least 10^{12} , it is

more or less inevitable or at least likely that such large populations will lead to a sub-population having such an interaction. The sub-population having such interaction may comprise at most 10^{10} cells, such as at most 10^9 cells, such as at most 10^8 , such as at most 10^7 cells, such as at most 10^6 cells, such as at most 10^5 cells, such as at most 10^4 cells, such as at most 10^3 cells, such as at most 10^2 cells or just 10 cells.

HOST CELLS

The host cells selected for this purpose are preferably cultivable under standard laboratory conditions using standard culture conditions, such as standard media and protocols. Preferably the host cells comprise a substantially stable cell line, in which the concatemers can be maintained for generations of cell division in a suitable manner. It is also of great advantage that standard techniques for transformation of the host cells are available, especially that methods are known for insertion of artificial chromosomes into the host cells. Host cells are also denoted producer cells.

It is also of advantage if the host cells are capable of undergoing meiosis to perform sexual recombination. It is also advantageous that meiosis is controllable through external manipulations of the cell culture. One especially advantageous host cell type is one where the cells can be manipulated through external manipulations into different mating types.

The host cell should preferably be conditionally deficient in the abilities to undergo homologous recombination. The host cell should preferably have a codon usage similar to that of the donor organisms. Furthermore, in the case of heterologous genomic DNA, if eukaryotic donor organisms are used, it is preferable that the host cell has the ability to process the donor messenger RNA properly, e.g., splice out introns.

The cells can be bacterial, archaebacteria, or eukaryotic and can constitute a homogeneous cell line or mixed culture. Suitable cells include the bacterial and eukaryotic cell lines commonly used in genetic engineering and protein expression. Suitable mammalian cells include those from, e.g., mouse, rat, hamster, primate, and human, both cell lines and primary cultures.

Preferred prokaryotic host organisms may include but are not limited to *Escherichia coli*, *Bacillus subtilis*, *B. licheniformis*, *B. cereus*, *Streptomyces lividans*, *Streptomyces coelicolor*, *Pseudomonas aeruginosa*, *Myxococcus xanthus*.
5 *Rhodococcus*, *Streptomyces*, *Actinomycetes*, *Corynebacteria*, *Bacillus*, *Pseudomonas*, *Salmonella*, and *Erwinia*. The complete genome sequences of *E. coli* and *Bacillus subtilis* are described by Blattner et al., *Science* 277, 1454-1462 (1997); Kunst et al., *Nature* 390, 249-256 (1997)).

10 Preferred eukaryotic host organisms are mammals, fish, insects, plants, algae and fungi.

Examples of mammalian cells include those from, e.g., monkey, mouse, rat, hamster, primate, and human, both cell lines and primary cultures. Preferred
15 mammalian host cells include but are not limited to those derived from humans, monkeys and rodents, such as chinese hamster ovary (CHO) cells, NIH/3T3, COS, 293, VERO, HeLa etc (see Kriegler M. in "Gene Transfer and Expression: A Laboratory Manual", New York, Freeman & Co. 1990), and stem cells, including embryonic stem cells and hemopoietic stem cells, zygotes, fibroblasts, lymphocytes,
20 kidney, liver, muscle, and skin cells.

Examples of insect cells include baculo lepidoptera.

Examples of plant cells include maize, rice, wheat, cotton, soybean, and sugarcane.
25 Plant cells such as those derived from *Nicotiana* and *Arabidopsis* are preferred

Examples of fungi include *penicillium*, *aspergillus*, such as *Aspergillus nidulans*, *podospora*, *neurospora*, such as *Neurospora crassa*, *saccharomyces*, such as *Saccharomyces cerevisiae* (budding yeast), *Schizosaccharomyces*, such as
30 *Schizosaccharomyces pombe* (fission yeast), *Pichia* spp, such as *Pichia pastoris*, and *Hansenula polymorpha* (methylotropic yeasts).

The choice of host will depend on a number of factors, depending on the intended use of the engineered host, including pathogenicity, substrate range, environmental
35 hardiness, presence of key intermediates, ease of genetic manipulation, and

likelihood of promiscuous transfer of genetic information to other organisms. Particularly advantageous hosts are *E. coli*, *Lactobacilli*, *Streptomyces*, *Actinomyces* and filamentous fungi.

5 A preferred host cell is yeast due to the following characteristics: it is fast growing, eukaryotic, allows scalable culture capabilities, genetic tools are available, it is metabolically flexible, can have a relatively permeable cell membrane/wall and folds more heterologous eukaryotic proteins correctly than prokaryotic cells.

10 Thus, an illustrative and not limiting list of suitable yeast host cells comprise: baker's yeast, *Kluyveromyces marxianus*, *K. lactis*, *Candida utilis*, *Phaffia rhodozyma*, *Saccharomyces boulardii*, *Pichia pastoris*, *Hansenula polymorpha*, *Yarrowia lipolytica*, *Candida paraffinica*, *Schwanniomyces castellii*, *Pichia stipitis*, *Candida shehatae*, *Rhodotorula glutinis*, *Lipomyces lipofer*, *Cryptococcus curvatus*, *Candida*
15 spp. (e.g. *C. palmiophila*), *Yarrowia lipolytica*, *Candida guilliermondii*, *Candida*, *Rhodotorula* spp., *Saccharomycopsis* spp., *Aureobasidium pullulans*, *Candida brumptii*, *Candida hydrocarbofumarica*, *Torulopsis*, *Candida tropicalis*, *Saccharomyces cerevisiae*, *Rhodotorula rubra*, *Candida flaveri*, *Eremothecium ashbyii*, *Pichia* spp., *Pichia pastoris*, *Schizosaccharomyces pombe* (fission yeast),
20 *Kluyveromyces*, *Hansenula*, *Kloeckera*, *Pichia*, *Pachysolen* spp., or *Torulopsis bombicola*.

Preferably, the host cell comprises at least one mutation in a central biosynthetic pathway. This mutation can be complemented by one or more selectable markers
25 inserted into the vector comprising the heterologous expressible nucleotide sequences so that cells containing the vector(s) can be selected.

In any one host cell it is possible to make all sorts of combinations of expressible nucleotide sequences from all possible sources. Furthermore, it is possible to make
30 combinations of promoters and/or spacers and/or introns and/or terminators in combination with one and the same expressible nucleotide sequence.

In a preferred embodiment the cells to be evolved are produced by inserting concatemers comprising the multitude of cassettes into a host cell, in which the
35 concatemers can be maintained and the expressible nucleotide sequences can be

expressed in a co-ordinated way. The cassettes comprised in the concatemers may be cut out from the host cell and re-assembled due to their uniform structure with – preferably – compatible restriction sites between the cassettes.

5 The cells as defined in the present invention are preferably collected into populations for use in the present invention. The composition of cells subjected to evolution is then produced by selecting cells from a population or from several sub-populations. A population of individual cells is a population of expression constructs prepared from randomly assembled or even concatenated expressible nucleotide
10 sequences derived from a plurality of species of donor organisms, in which expressible nucleotide sequences are operably associated with regulatory regions that drives expression of the expressible nucleotide sequences in an appropriate host cell. The host cells used are capable of producing functional gene products of the donor organisms. Upon expression in the host cell, gene products of the donor
15 organism(s) may interact to form novel biochemical pathways.

The population according to this embodiment of the invention may in any one cell comprise a unique and preferably random combination of a high number of expression cassettes being heterologous to the host cells. Through this random
20 combination of expression cassettes novel and unique combinations of gene products are obtained in each cell. Such populations are especially adapted in the discovery of novel metabolic pathways created through the non-native combinations of gene products.

25 In a preferred embodiment a population may be defined as a population comprising a collection of individual cells, the cells being denoted

cell₁, cell₂, ..., cell_i, wherein $i \geq 2$,

each cell comprising at least one concatemer of individual oligonucleotide cassettes, each concatemer comprising an oligonucleotide of the following
30 formula:

$$[rs_2\text{-SP-PR-X-TR-SP-rs}_1]_n$$

wherein rs₁ and rs₂ together denote a restriction site, SP denotes a spacer of at least two bases, X denotes an expressible nucleotide sequence, PR denotes a promoter capable of functioning in said cell, capable of regulating the expression
35 of X in said cell, TR denotes a terminator, and $n \geq 2$, and

wherein at least one concatemer of cell₁ is different from a concatemer of cell₂.

In the present context the nucleotide sequence of the formula [rs₂-SP-PR-X-TR-SP-rs₁]_n is also referred to as an expression cassette of the formula [rs₂-SP-PR-X-TR-SP-rs₁]_n.

Sub-populations may comprise cells as defined above for populations, but mostly the cells of a sub-population will have at least one trait in common, such as common promoter combinations, genetic material from a common species, a common phenotype or the like.

The function of the populations and sub-populations is to act as a source of diversity when obtaining the composition of cells to be evolved. Thus, in one embodiment the composition is a collection of subcompositions, wherein a subcomposition is a collection of individual cells having at least one phenotype in common. In a preferred embodiment the composition comprises at least 2 individual subcompositions, said subcompositions being different, such as at least 5 individual sub-compositions, such as at least 10 individual sub-compositions, wherein each sub-composition comprises at least 10 genetically different cells, such as at least 50 genetically different cells, such as at least 100 genetically different cells, such as at least 10³ genetically different cells, such as at least 10⁴ genetically different cells, such as at least 10⁵ genetically different cells, such as at least 10⁶ genetically different cells, such as at least 10⁷ genetically different cells, such as at least 10⁸ genetically different cells, such as at least 10⁹ genetically different cells.

The composition of cells preferably comprises at least 20 genetically different cells, such as at least 50 genetically different cells, such as at least 100 genetically different cells, such as at least 150 genetically different cells, such as at least 200 genetically different cells, such as at least 250 genetically different cells, such as at least 500 genetically different cells, such as at least 750 genetically different cells, such as at least 1000 genetically different cells, such as at least 10⁴ genetically different cells, such as at least 10⁵ genetically different cells, such as at least 10⁶ genetically different cells, such as at least 10⁷ genetically different cells, such as at least 10⁸ genetically different cells, such as at least 10⁹ genetically different cells.

In a preferred embodiment at least a majority of the individual cells have different genetic patterns or genotypes, thereby representing a great diversity.

5 The term "founding population" or a "founder populations" shall mean a Cell Population that has not itself been subjected to a selection round, in the present context also referred to as composition of cells. Optionally the expression constructs within the cell population are constructed such that genetic material from species that are known from prior art to produce compounds of a desired structure class, or compounds that have a desired functional effect, or are associated with a desired
10 functional effect independent of knowledge of the compounds, predominate.

The term "daughter population" is a cell population having been subjected to at least one selection round. In the present context the daughter population is also referred to as a further modified composition.

15

Controlling The Genetic Basis of the Diversity

Sources of Genes

20 The natural world contains a significant amount of genetic diversity. Various authorities estimate that there are at least 10^7 different species, and that each of these species contains on average at least 10^4 genes. Even allowing for the fact that many of these genes are relatively conserved between species this represents a high level of genetic diversity.

25

One approach that can be envisaged for the purposes of the current invention is to source genetic material so as to maximise the taxonomic diversity of the genes obtained.

30 A second is to preferentially source genetic material from organisms that are known or reputed to produce molecules of the structural class or with the functional effects desired or are known or reputed to have a desired functional effect without the molecule being known, or are taxonomically related to any such organism.

35 A third approach is selection of genes of particular interest.

A fourth approach is to select genes that generally extend the host metabolic pathways.

5 Optionally these approaches can be combined in any suitable manner.

Genes can be sourced through the collection and processing of genetic material of various forms. The expressible nucleotide sequences that can be inserted into the vectors, concatemers, and cells according to this invention encompass any type of
10 nucleotide such as RNA, DNA. Such a nucleotide sequence could be obtained e.g. from cDNA, which by its nature is expressible. But it is also possible to use sequences of genomic DNA, coding for specific genes. Preferably, the expressible nucleotide sequences correspond to full length genes such as substantially full length cDNA, but nucleotide sequences coding for shorter peptides than the original
15 full length clones may also be used. Shorter peptides may still retain the catalytic activity of the native proteins. Thus, a preferred embodiment of this invention is to source and collect messenger transcripts (mRNA) for obtaining cDNA.

Another way to obtain expressible nucleotide sequences is through chemical
20 synthesis of nucleotide sequences coding for known peptide or protein sequences. Thus the expressible DNA sequences does not have to be a naturally occurring sequence, although it may be preferable for practical purposes to primarily use naturally occurring nucleotide sequences. Whether the DNA is single or double stranded will depend on the vector system used.

25 By the term "Expression state" is meant a state of gene expression (i.e the mRNA transcript population) in a specific cell, tissue, combination of tissues or organism or organisms of a given species as sampled at any one time. Different expression states are found in different individuals, or in the same individual at different point in time, or in the same individual at different points its life-cycle or in the same individual under differing external conditions. The expression states of given cells or
30 tissues of a given individual will also vary with respect to other cells or tissues of the same individual. Different expression states may also be obtained in the same organ or tissue in any one species or individual by exposing the tissues or organs to
35 different environmental conditions comprising but not limited to changes in

developmental stage, age, disease, infection, drought, humidity, salinity, exposure to xenobiotics, physiological effectors, temperature, pressure, pH, light, gaseous environment, chemicals such as toxins.

5 In the following the invention is described in the order in which the steps of obtaining a transformed host cell containing an evolvable artificial chromosome may be performed, starting with the entry vector.

10 In most cases the orientation with respect to the promoter of an expressible nucleotide sequence will be such that the coding strand is transcribed into a proper mRNA. It is however conceivable that the sequence may be reversed generating an antisense transcript in order to block expression of a specific gene.

15 Each cell of the *cell population* is initially produced by combining genes selected from at least one expression state. It is of course also possible from the onset to combine genes from two, three, four or more expression states in one host cell or to combine genes from different organisms in one cell. In some embodiments of the invention it is preferred to combine genes from a large variety of organisms into a single host in a manner so that each cell comprises at least two expressible
20 nucleotide sequences, said sequences being heterologous to the cell, i.e. the sequences are not found in the native cell type.

A wide variety of combinations of expressible nucleotide sequences from all possible sources may occur in the cells. Furthermore, it is possible to make
25 combinations of promoters and/or spacers and/or introns and/or terminators in combination with one and the same expressible nucleotide sequence.

Thus in any one cell there may preferably be expressible nucleotide sequences from two different expression states. Furthermore, these two different expression states
30 may be from one species or advantageously from two different species. Any one host cell may also comprise expressible nucleotide sequences from at least three species, such as from at least four, five, six, seven, eight, nine or ten species, or from more than 15 species such as from more than 20 species, for example from more than 30, 40 or 50 species, such as from more than 100 different species, for
35 example from more than 300 different species, such as from more than 500 different

species, for example from more than 750 different species, thereby obtaining combinations of large numbers of expressible nucleotide sequences from a large number of species. In this way potentially unlimited numbers of combinations of expressible nucleotide sequences can be combined across different expression states. These different expression states may represent at least two different tissues, such as at least two organs, such as at least two species, such as at least two genera. The different species may be from at least two different phylae, such as from at least two different classes, such as from at least two different divisions, more preferably from at least two different sub-kingdoms, such as from at least two different kingdoms. Thus expressible nucleotide sequences may be combined from a eukaryote and a prokaryote into one and the same cell.

According to another embodiment of the invention, the expressible nucleotide sequences may be from one and the same expression state. The products of these sequences may interact with the products of the genes in the host cell and with each other and form new enzyme combinations leading to novel biochemical pathways.

Sources of genetic diversity

Examples of groups of species and individual species known to produce compounds with structural or functional utility include without limitation

25	Bacteria	Streptomyces , Micromonospora, Norcadia, Actinomadura, Actinoplanes, Streptosporangium, Microbispora, Kitasatosporium, Azobacterium, Rhizobium, Achromobacterium, Enterobacterium, Brucella, Micrococcus, Lactobacillus, Bacillus (B.t. toxins), Clostridium (toxins), Brevibacterium, Pseudomonas, Aerobacter, Vibrio, Halobacterium, Mycoplasma, Cytophaga, Myxococcus
30	Fungi	Amanita muscaria (fly agaric, ibotenic acid, muscimol), Psilocybe (psilocybin) Physarium, Fuligo, Mucor, Phytophthora, Rhizopus, Aspergillus, Penicillium (penicillin), Coprinus, Phanerochaete, Acremonium (Cephalosporin), Trochoderma, Helminthosporium, Fusarium, Alternaria, Myrothecium, Saccharomyces
35	Algae	Digenea simplex (kainic acid, antihelminthic), Laminaria anqustata (laminine, hypotensive)
	Lichens	Usnea fasciata (vulpinicacid, antimicrobial; usnic acid, antitumor)

82

5	Higher Plants	Artemisia (artemisinin), Coleus (forskolin), Desmodium (K channel agonist), Catharanthus (Vinca alkaloids), Digitalis (cardiac glycosides), Podophyllum (podophyllotoxin), Taxus (taxol), Cephalotaxus (homoharringtonine), Camptotheca (Camptothecin), Camellia sinensis (Tea), Cannabis indica, Cannabis sativa (Hemp), Erythroxylum coca (Coca), Lophophora williamsii (Peyote), Myristica fragrans (Nutmeg), Nicotiana, Papaver somniferum (Opium Poppy), Phalaris arundinacea (Reed canary grass)
10	Protozoa	Ptychodiscus brevis; Dinoflagellates (brevitoxin, cardiovascular)
	Sponges	Microciona prolifera (ectyonin, antimicrobial) Cryptotethya crypta (D-arabino furanosides)
15	Coelenterata	Portuguese Man o War & other jellyfish and medusoid toxins.
	Corals	Pseudoterogonia species (Pseudoteracins, anti-inflammatory), Erythropodium (erythrolides, anti-inflammatory)
20	Aschelminths	Nematode secretory compounds
	Molluscs	Conus toxins, sea slug toxins, cephalopod neurotransmitters, squid inks
	Annelida	Lumbriconereis heteropa (nereistoxin, insecticidal)
25	Arachnids	Dolomedes ("fishing spider" venoms)
	Crustacea	Xenobalanus (skin adhesives)
30	Insects	Epilachna (mexican bean beetle alkaloids)
	Spinunculida	Bonellia viridis (bonellin, neuroactive)
	Bryozoans	Bugula neritina (bryostatins, anti cancer)
35	Echinoderms	Crinoid chemistry
	Tunicates	Trididemnum solidum (didemnins, anti-tumor and anti-viral; Ecteinascidia turbinata ecteinascidins, anti-tumor)
40	Vertebrates	Eptatretus stoutii (eptatretin, cardioactive), Trachinus draco (proteinaceous toxins, reduce blood pressure, respiration and reduce heart rate). Dendrobatid frogs (batrachotoxins, pumiliotoxins, histrionicotoxins, and other polyamines); Snake venom toxins; Orinithorhynchus anatinus (duck-billed platypus venom), modified

carotenoids, retinoids and steroids; Avians: histrionicotoxins, modified carotenoids, retinoids and steroids

Controlling Gene Expression - Expression Cassettes

5

Genes primarily give rise to selectable phenotypes through transcription of the gene to RNA and translation of the RNA to protein. Furthermore phenotypes are often the result of interactions between multiple genes and their gene products

10

Thus it is an element of the current invention that the heterologous genes are provided in a format whereby their individual and collective expression (transcription to RNA) can be controlled.

15

It is likely that through the combination of a high number of non-native genes in a host cell combinations of genes or single genes are inserted that are lethal or sub-lethal to the host cell. Through the co-ordinated expression of the genes in the host cell it is possible not only to initiate the expression of any subset of genes but also to repress such expression, e.g. of lethal or sub-lethal genes.

20

Through external regulation of the promoters controlling the expressible nucleotide sequences novel and non-naturally occurring combinations of expressed genes can be obtained. Since these novel and non-natural combinations of gene products are found in one and the same cell, the heterologous gene products may affect the metabolism of the host cell in novel ways and thus cause it to produce novel primary or secondary metabolites and/or known metabolites in novel amounts and/or known metabolites in novel compartments of the cell or outside the cells. The novel metabolic pathways and/or novel or modified metabolites may be obtained without substantially recombining the introduced genes with a segment in the host genome or an episome of the host cells by as well as without intra- or extra concatemeric recombination.

30

35

By having expressible nucleotide sequences under the control of a number of independently inducible or repressible promoters, a large number of different expression states can be created inside one single cell by selectively turning on and off groups of the inserted expressible nucleotide sequences. The number of

independently inducible and/or repressible promoters in one cell may vary from 1 to 10, such as 2, 3, 4, 5, 6, 7, 8, or 9, or even up to 15, 20, 25 or above 50 promoters.

5 In the evolution steps the functionality of the controllable promoters of the cells is used, since due to the controllable promoters it is possible during the screening and selection step to switch promoters on and off, thereby creating a greater diversity of expressed genes.

10 The term promoter is used with its normal meaning, i.e. a DNA sequence to which RNA polymerase binds and initiates transcription. The promoter determines the polarity of the transcript by specifying which strand will be transcribed.

- Bacterial promoters normally consist of -35 and -10 (relative to the transcriptional start) consensus sequences which are bound by a specific sigma factor and RNA polymerase.
- 15 • Eukaryotic promoters are more complex. Most promoters utilized in expression vectors are transcribed by RNA polymerase II. General transcription factors (GTFs) first bind specific sequences near the transcriptional start and then recruit the binding of RNA polymerase II. In addition to these minimal promoter elements, small sequence elements are
20 recognized specifically by modular DNA-binding / trans-activating proteins (e.g. AP-1, SP-1) which regulate the activity of a given promoter.
- Viral promoters may serve the same function as bacterial and eukaryotic promoters. Upon viral infection of their host, viral promoters direct
25 transcription either by using host transcriptional machinery or by supplying virally encoded enzymes to substitute part of the host machinery. Viral promoters are recognised by the transcriptional machinery of a large number of host organisms and are therefore often used in cloning and expression vectors.

30 Promoters may furthermore comprise regulatory elements, which are DNA sequence elements which act in conjunction with promoters and bind either repressors (e.g., lacO/ LAC Iq repressor system in E. coli) or inducers (e.g., gal1 /GAL4 inducer system in yeast). In either case, transcription is virtually "shut off" until the promoter is derepressed or induced, at which point transcription is "turned-
35 on". The choice of promoter in the cassette is primarily dependent on the host

organism into which the cassette is intended to be inserted. An important requirement to this end is that the promoter should preferably be capable of functioning in the host cell, in which the expressible nucleotide sequence is to be expressed.

5

Preferably the promoter is an externally controllable promoter, such as an inducible promoter and/or a repressible promoter. The promoter may be either controllable (repressible/inducible) by chemicals such as the absence/presence of chemical inducers, e.g. metabolites, substrates, metals, hormones, sugars. The promoter may likewise be controllable by certain physical parameters such as temperature, pH, redox status, growth stage, developmental stage, or the promoter may be inducible/repressible by a synthetic inducer/repressor such as the gal inducer.

10

In order to avoid unintentional interference with the gene regulation systems of the host cell, and in order to improve controllability of the co-ordinated gene expression the promoter is preferably a synthetic promoter. Suitable promoters are described in US 5,798,227, US 5,667,986. Principles for designing suitable synthetic eukaryotic promoters are disclosed in US 5,559,027, US 5,877,018 or US 6,072,050.

15

Synthetic inducible eukaryotic promoters for the regulation of transcription of a gene may achieve improved levels of protein expression and lower basal levels of gene expression. Such promoters preferably contain at least two different classes of regulatory elements, usually by modification of a native promoter containing one of the inducible elements by inserting the other of the inducible elements. For example, additional metal responsive elements (IREs) and/or glucocorticoid responsive elements (GREs) may be provided to native promoters. Additionally, one or more constitutive elements may be functionally disabled to provide the lower basal levels of gene expression.

25

Preferred examples of promoters include but is not limited to those promoters being induced and/or repressed by any factor selected from the group comprising carbohydrates, e.g. galactose; low inorganic phosphate levels; temperature, e.g. low or high temperature shift; metals or metal ions, e.g. copper ions; hormones, e.g. dihydrotestosterone; deoxycorticosterone; heat shock (e.g. 39°C); methanol; redox-status; growth stage, e.g. developmental stage; synthetic inducers, e.g. gal inducer.

35

Examples of such promoters include ADH 1, PGK 1, GAP 491, TPI, PYK, ENO, PMA 1, PHO5, GAL 1, GAL 2, GAL 10, MET25, ADH2, MEL 1, CUP 1, HSE, AOX, MOX, SV40, CaMV, Opaque-2, GRE, ARE, PGK/ARE hybrid, CYC/GRE hybrid, TPI/ α 2 operator, AOX 1, MOX A.

5

More preferably, however the promoter is selected from hybrid promoters such as PGK/ARE hybrid, CYC/GRE hybrid or from synthetic promoters. Such promoters can be controlled without interfering too much with the regulation of native genes in the expression host.

10

In the following, examples of known yeast promoters that may be used in conjunction with the present invention are shown. The examples are by no way limiting and only serve to indicate to the skilled practitioner how to select or design promoters that are useful according to the present invention.

15

Although numerous transcriptional promoters which are functional in yeasts have been described in the literature, only some of them have proved effective for the production of polypeptides by the recombinant route. There may be mentioned in particular the promoters of the PGK genes (3-phosphoglycerate kinase, TDH genes encoding GAPDH (Glyceraldehyde phosphate dehydrogenase), TEF1 genes (Elongation factor 1), MF α 1 (α sex pheromone precursor) which are considered as strong constitutive promoters or alternatively the regulatable promoter CYC1 which is repressed in the presence of glucose or PHO5 which can be regulated by thiamine. However, for reasons which are often unexplained, they do not always allow the effective expression of the genes which they control. In this context, it is always advantageous to be able to have new promoters in order to generate new effective host/vector systems. Furthermore, having a choice of effective promoters in a given cell also makes it possible to envisage the production of multiple proteins in this same cell (for example several enzymes of the same metabolic chain) while avoiding the problems of recombination between homologous sequences.

25

30

In general, a promoter region is situated in the 5' region of the genes and comprises all the elements allowing the transcription of a DNA fragment placed under their control, in particular:

- 5 (1) a so-called minimal promoter region comprising the TATA box and the site of initiation of transcription, which determines the position of the site of initiation as well as the basal level of transcription. In *Saccharomyces cerevisiae*, the length of the minimal promoter region is relatively variable. Indeed, the exact location of the TATA box varies from one gene to another and may be situated from -40 to -120 nucleotides upstream of the site of the initiation (Chen and Struhl, 1985, EMBO J., 4, 3273-3280)
- 10 (2) sequences situated upstream of the TATA box (immediately upstream up to several hundreds of nucleotides) which make it possible to ensure an effective level of transcription either constitutively (relatively constant level of transcription all along the cell cycle, regardless of the conditions of culture) or in a regulatable manner (activation of transcription in the presence of an activator and/or repression in the presence of a repressor). These sequences, may be of several types: activator, inhibitor, enhancer, inducer, repressor and may respond to
- 15 cellular factors or varied culture conditions.

Examples of such promoters are the ZZA1 and ZZA2 promoters disclosed in US 5,641,661, the EF1- α protein promoter and the ribosomal protein S7 gene promoter disclosed in WO 97/44470,, the COX 4 promoter and two unknown promoters (SEQ ID No: 1 and 2 in the document) disclosed in US 5,952,195. Other useful promoters include the HSP150 promoter disclosed in WO 98/54339 and the SV40 and RSV promoters disclosed in US 4,870,013 as well as the PyK and GAPDH promoters disclosed in EP 0 329 203 A1.

25 More preferably the invention employs the use of synthetic promoters. Synthetic promoters are often constructed by combining the minimal promoter region of one gene with the upstream regulating sequences of another gene. Enhanced promoter control may be obtained by modifying specific sequences in the upstream regulating sequences, e.g. through substitution or deletion or through inserting multiple copies

30 of specific regulating sequences. One advantage of using synthetic promoters is that they can be controlled without interfering too much with the native promoters of the host cell.

One such synthetic yeast promoter comprises promoters or promoter elements of two different yeast-derived genes, yeast killer toxin leader peptide, and amino terminus of IL-1 β (WO 98/54339).

5 Another example of a yeast synthetic promoter is disclosed in US 5,436,136 (Hinnen et al), which concerns a yeast hybrid promoter including a 5' upstream promoter element comprising upstream activation site(s) of the yeast PHO5 gene and a 3' downstream promoter element of the yeast GAPDH gene starting at nucleotide -300 to -180 and ending at nucleotide -1 of the GAPDH gene.

10

Another example of a yeast synthetic promoter is disclosed in US 5,089,398 (Rosenberg et al). This disclosure describes a promoter with the general formula - (P.R.(2)-P.R.(1))-

wherein:

15 P.R.(1) is the promoter region proximal to the coding sequence and having the transcription initiation site, the RNA polymerase binding site, and including the TATA box, the CAAT sequence, as well as translational regulatory signals, e.g., capping sequence, as appropriate;

20 P.R.(2) is the promoter region joined to the 5'-end of P.R.(1) associated with enhancing the efficiency of transcription of the RNA polymerase binding region;

In US 4,945,046 (Horii et al) discloses a further example of how to design a synthetic yeast promoter. This specific promoter comprises promoter elements derived both from yeast and from a mammal. The hybrid promoter consists essentially of *Saccharomyces cerevisiae* PHO5 or GAP-DH promoter from which the upstream activation site (UAS) has been deleted and replaced by the early enhancer region derived from SV40 virus.

25

30 Co-ordinated expression of gene subsets can also be utilised to identify which heterologous genes are responsible for the production of a given phenotype.

In the following the sequence of steps to be taken when starting with the isolation of mRNA until insertion to an entry vector for providing the cells according to the invention is described. In short the sequence may include the following steps

35

i) isolating mRNA from an expression state,

- ii) obtaining substantially full length cDNA clones corresponding to the mRNA sequences,
- iii) inserting the substantially full length cDNA clones into a cloning site in a cassette in a primary vector, said cassette being of the general formula in 5'→3' direction:
- [RS1-RS2-SP-PR-CS-TR-SP-RS2'-RS1']
- wherein CS denotes a cloning site.

Expression cassettes

The expression cassettes according to the present invention are preferably arranged as a cassette of nucleotides in a highly ordered sequence, the cassette having the general formula in 5'→3' direction:

[RS1-RS2-SP-PR-CS-TR-SP-RS2'-RS1']

wherein RS1 and RS1' denote restriction sites, RS2 and RS2' denote restriction sites different from RS1 and RS1', SP denotes a spacer sequence of at least two nucleotides, PR denotes a promoter, CS denotes a cloning site, and TR denotes a terminator, all of them being as discussed elsewhere in this specification.

It is an advantage to have two different restriction sites flanking both sides of the expression construct. By treating the primary vectors with restriction enzymes cleaving both restriction sites, the expression construct and the primary vector will be left with two non-compatible ends. This facilitates a concatenation process, since the empty vectors do not participate in the concatenation of expression constructs.

In principle, any restriction site, for which a restriction enzyme is known can be used. These include the restriction enzymes generally known and used in the field of molecular biology such as those described in Sambrook, Fritsch, Maniatis, "A laboratory Manual", 2nd edition. Cold Spring Harbor Laboratory Press, 1989.

The restriction site recognition sequences preferably are of a substantial length, so that the likelihood of occurrence of an identical restriction site within the cassette is minimised. Thus the first restriction site may comprise at least 6 bases, but more preferably the recognition sequence comprises at least 7 or 8 bases. Restriction sites having 7 or more non N bases in the recognition sequence are generally

known as "rare restriction sites" (see example 17). However, the recognition sequence may also be at least 10 bases, such as at least 15 bases, for example at least 16 bases, such as at least 17 bases, for example at least 18 bases, such as at least 18 bases, for example at least 19 bases, for example at least 20 bases, such as at least 21 bases, for example at least 22 bases, such as at least 23 bases, for example at least 25 bases, such as at least 30 bases, for example at least 35 bases, such as at least 40 bases, for example at least 45 bases, such as at least 50 bases.

Preferably the first restriction site RS1 and RS1' is recognised by a restriction enzyme generating blunt ends of the double stranded nucleotide sequences. By generating blunt ends at this site, the risk that the vector participates in a subsequent concatenation is greatly reduced. The first restriction site may also give rise to sticky ends, but these are then preferably non-compatible to the sticky ends resulting from the second restriction site, RS2 and RS2'.

According to a preferred embodiment of the invention, the second restriction site, RS2 and RS2' comprises a rare restriction site. Thus, the longer the recognition sequence of the rare restriction site the more rare it is and the less likely is it that the restriction enzyme recognising it will cleave the nucleotide sequence at other – undesired – positions.

The rare restriction site may furthermore serve as a PCR priming site. Thereby it is possible to copy the cassettes via PCR techniques and thus indirectly "excise" the cassettes from a vector.

Single-stranded compatible ends may be created by digestion with restriction enzymes. For concatenation a preferred enzyme for excising the cassettes would be a rare cutter, i.e. an enzyme that recognises a sequence of 7 or more nucleotides. Examples of enzymes that cut very rarely are the meganucleases, many of which are intron encoded, like e.g. I-Ceu I, I-Sce I, I-Ppo I, and PI-Psp I (see example 17d for more). Other preferred enzymes recognize a sequence of 8 nucleotides like e.g. Asc I, AsiS I, CciN I, CspB I, Fse I, MchA I, Not I, Pac I, Sbf I, Sda I, Sgf I, SgrA I, Sse232 I, and Sse8387 I, all of which create single stranded, palindromic compatible ends.

Other preferred rare cutters, which may also be used to control orientation of individual cassettes in the concatemer are enzymes that recognize non-palindromic sequences like e.g. Aar I, Sap I, Sfi I, Sdi I, and Vpa (see example 17c for more).

5 Alternatively, cassettes can be prepared by the addition of restriction sites to the ends, e.g. by PCR or ligation to linkers (short synthetic dsDNA molecules). Restriction enzymes are continuously being isolated and characterised and it is anticipated that many of such novel enzymes can be used to generate single-stranded compatible ends according to the present invention.

10

It is conceivable that single stranded compatible ends can be made by cleaving the vector with synthetic cutters. Thus, a reactive chemical group that will normally be able to cleave DNA unspecifically can cut at specific positions when coupled to another molecule that recognises and binds to specific sequences. Examples of molecules that recognise specific dsDNA sequences are DNA, PNA, LNA, phosphothioates, peptides, and amides. See e.g. Armitage, B.(1998) Chem. Rev. 98: 1171-1200, who describes photocleavage using e.g. anthraquinone and UV light; Dervan P.B. & Bürlí R.W. (1999) Curr. Opin. Chem. Biol. 3: 688-93 describes the specific binding of polyamides to DNA; Nielsen, P.E. (2001) Curr. Opin. Biotechnol. 12: 16-20 describes the specific binding of PNA to DNA, and Chemical Reviews special thematic issue: RNA/DNA Cleavage (1998) vol. 98 (3) Bashkin J.K. (ed.) ACS publications, describes several examples of chemical DNA cleavers.

15

20

Single-stranded compatible ends may also be created e.g. by using PCR primers including dUTP and then treating the PCR product with Uracil-DNA glycosylase (Ref: US 5,035,996) to degrade part of the primer. Alternatively, compatible ends can be created by tailing both the vector and insert with complimentary nucleotides using Terminal Transferase (Chang, LMS, Bollum TJ (1971) J Biol Chem 246:909).

25

30 The spacer sequence located between the RS2 and the PR sequence is preferably a non-transcribed spacer sequence. The purpose of the spacer sequence(s) is to minimise recombination between different concatemers present in the same cell or between cassettes present in the same concatemer, but it may also serve the purpose of making the nucleotide sequences in the cassettes more "host" like. A further purpose of the spacer sequence is to reduce the occurrence of hairpin formation

35

between adjacent palindromic sequences, which may occur when cassettes are assembled head to head or tail to tail. Spacer sequences may also be convenient for introducing short conserved nucleotide sequences that may serve e.g. as PCR primer sites or as target for hybridization to e.g. nucleic acid or PNA or LNA probes allowing affinity purification of cassettes.

The cassette may also optionally comprise another spacer sequence of at least two nucleotides between TR and RS2. When cassettes are cut out from a vector and concatenated into concatemers of cassettes, the spacer sequences together ensure that there is a certain distance between two successive identical promoter or terminator sequences. This distance may comprise at least 50 bases, such as at least 60 bases, for example at least 75 bases, such as at least 100 bases, for example at least 150 bases, such as at least 200 bases, for example at least 250 bases, such as at least 300 bases, for example at least 400 bases, for example at least 500 bases, such as at least 750 bases, for example at least 1000 bases, such as at least 1100 bases, for example at least 1200 bases, such as at least 1300 bases, for example at least 1400 bases, such as at least 1500 bases, for example at least 1600 bases, such as at least 1700 bases, for example at least 1800 bases, such as at least 1900 bases, for example at least 2000 bases, such as at least 2100 bases, for example at least 2200 bases, such as at least 2300 bases, for example at least 2400 bases, such as at least 2500 bases, for example at least 2600 bases, such as at least 2700 bases, for example at least 2800 bases, such as at least 2900 bases, for example at least 3000 bases, such as at least 3200 bases, for example at least 3500 bases, such as at least 3800 bases, for example at least 4000 bases, such as at least 4500 bases, for example at least 5000 bases, such as at least 6000 bases.

The number of the nucleotides between the spacer located 5' to the PR sequence and the one located 3' to the TR sequence may be any. However, it may be advantageous to ensure that at least one of the spacer sequences comprises between 100 and 2500 bases, preferably between 200 and 2300 bases, more preferably between 300 and 2100 bases, such as between 400 and 1900 bases, more preferably between 500 and 1700 bases, such as between 600 and 1500 bases, more preferably between 700 and 1400 bases.

If the intended host cell is yeast, the spacers present in a concatemer should preferably comprise a combination of a few ARSes with varying lambda phage DNA fragments.

- 5 Preferred examples of spacer sequences include but are not limited to: Lambda phage DNA, prokaryotic genomic DNA such as E. coli genomic DNA, ARSes.

The cloning site in the cassette in the primary vector should be designed so that any nucleotide sequence can be cloned into it.

10

The cloning site in the cassette preferably allows directional cloning. Hereby is ensured that transcription in a host cell is performed from the coding strand in the intended direction and that the translated peptide is identical to the peptide for which the original nucleotide sequence codes.

15

However according to some embodiments it may be advantageous to insert the sequence in opposite direction. According to these embodiments, so-called antisense constructs may be inserted which prevent functional expression of specific genes involved in specific pathways. Thereby it may become possible to divert metabolic intermediates from a prevalent pathway to another less dominant pathway.

20

The cloning site in the cassette may comprise multiple cloning sites, generally known as MCS or polylinker sites, which is a synthetic DNA sequence encoding a series of restriction endonuclease recognition sites. These sites are engineered for convenient cloning of DNA into a vector at a specific position and for directional cloning of the insert.

25

Cloning of cDNA does not have to involve the use of restriction enzymes. Other alternative systems include but are not limited to:

30

- Creator™ Cre-loxP system from Clontech, which uses recombination and loxP sites
- use of Lambda attachment sites (att-λ), such as the Gateway™ system from Life Technologies.

35

Both of these systems are directional.

The role of the terminator sequence is to limit transcription to the length of the coding sequence. An optimal terminator sequence is thus one, which is capable of performing this act in the host cell.

5

In prokaryotes, sequences known as transcriptional terminators signal the RNA polymerase to release the DNA template and stop transcription of the nascent RNA.

10

In eukaryotes, RNA molecules are transcribed well beyond the end of the mature mRNA molecule. New transcripts are enzymatically cleaved and modified by the addition of a long sequence of adenylic acid residues known as the poly-A tail. A polyadenylation consensus sequence is located about 10 to 30 bases upstream from the actual cleavage site.

15

Preferred examples of yeast derived terminator sequences include, but are not limited to: ADN1, CYC1, GPD, ADH1 alcohol dehydrogenase.

20

Depending on the nature of the host cell, it may be advantageous that at least one cassette comprises an intron between the promoter and the expressible nucleotide sequence, more preferable that substantially all cassettes comprise an intron between the promoter and the expressible nucleotide sequence. The choice of intron sequence depends on requirements of the host cell.

25

Thus, optionally the cassette in the vector comprises an intron sequence, which may be located 5' or 3' to the expressible nucleotide sequence. The design and layout of introns is well known in the art. The choice of intron design largely depends on the intended host cell, in which the expressible nucleotide sequence is eventually to be expressed. The effects of having intron sequence in the expression cassettes are those generally associated with intron sequences.

30

35

Examples of yeast introns can be found in the literature and in specific databases such as Ares Lab Yeast Intron Database (Version 2.1) as updated on 15 April 2000. Earlier versions of the database as well as extracts of the database have been published in: "Genome-wide bioinformatic and molecular analysis of introns in *Saccharomyces cerevisiae*." by Spingola M, Grate L, Haussler D, Ares M Jr. (RNA

1999 Feb;5(2):221-34) and "Test of intron predictions reveals novel splice sites, alternatively spliced mRNAs and new introns in meiotically regulated genes of yeast." by Davis CA, Grate L, Spingola M, Ares M Jr, (Nucleic Acids Res 2000 Apr 15;28(8):1700-6).

5

Primary vectors (entry vectors)

By the term entry vector is meant a vector for storing and amplifying cDNA or other expressible nucleotide sequences using the cassettes according to the present invention. The entry vectors or primary vectors are preferably able to propagate in E. coli or any other suitable standard host cell. It should preferably be amplifiable and amenable to standard normalisation and enrichment procedures.

The entry vector may be of any type of DNA that has the basic requirements of a) being able to replicate itself in at least one suitable host organism and b) allows insertion of foreign DNA which is then replicated together with the vector and c) preferably allows selection of vector molecules that contain insertions of said foreign DNA. In a preferred embodiment the vector is able to replicate in standard hosts like yeasts, bacteria and it should preferably have a high copy number per host cell. It is also preferred that the vector in addition to a host specific origin of replication, contains an origin of replication for a single stranded virus, such as e.g. the f1 origin for filamentous phages. This will allow the production of single stranded nucleic acid which may be useful for normalisation and enrichment procedures of cloned sequences. A vast number of cloning vectors have been described which are commonly used and references may be given to e.g. Sambrook, J; Fritsch, E.F; and Maniatis T. (1989) Molecular Cloning: A laboratory manual. Cold Spring Harbour Laboratory Press, USA, Netherlands Culture Collection of Bacteria (www.cbs.knaw.nl/NCCB/collection.htm) or Department of Microbial Genetics, National Institute of Genetics, Yata 1111 Mishima Shizuoka 411-8540, Japan (www.shigen.nig.ac.jp/cvector/cvector.html). A few type-examples that are the parents of many popular derivatives are M13mp10, pUC18, Lambda gt 10, and pYAC4. Examples of primary vectors include but are not limited to M13K07, pBR322, pUC18, pUC19, pUC118, pUC119, pSP64, pSP65, pGEM-3, pGEM-3Z, pGEM-3Zf(-), pGEM-4, pGEM-4Z, π AN13, pBluescript II, CHARON 4A, λ^+ , CHARON 21A, CHARON 32, CHARON 33, CHARON 34, CHARON 35, CHARON

40, EMBL3A, λ 2001, λ DASH, λ FIX, λ gt10, λ gt11, λ gt18, λ gt20, λ gt22, λ ORF8, λ ZAP/R, pJB8, c2RB, pcos1EMBL

5 Methods for cloning of cDNA or genomic DNA into a vector are well known in the art. Reference may be given to J. Sambrook, E.F. Fritsch, T. Maniatis: Molecular Cloning, A Laboratory Manual (2nd edition, Cold Spring Harbor Laboratory Press, 1989).

10 One example of a circular model entry vector is described in Figure 10. The vector, EVE contains the expression cassette, R1-R2-Spacer-Promoter-Multi Cloning Site-Terminator-Spacer-R2-R1. The vector furthermore contains a gene for ampicillin resistance, AmpR, and an origin of replication for E.coli, ColE1.

15 The entry vectors EVE4, EVE5, and EVE8 shown in Figures 11, 12, and 13. These all contain SrfI as R1 and Ascl as R2. Both of these sites are palindromic and are regarded as rare restriction sites having 8 bases in the recognition sequence. The vectors furthermore contain the AmpR ampicillin resistance gene, and the ColE1 origin or replication for E.coli as well as f1, which is an origin of replication for filamentous phages, such as M13. EVE4 (Fig. 11) contains the MET25 promoter and the ADH1 terminator. Spacer 1 and spacer 2 are short sequences deriving from the multiple cloning site, MCS. EVE5 (Fig. 12) contains the CUP1 promoter and the ADH1 terminator. EVE8 (Fig. 13) contains the CUP1 promoter and the ADH1 terminator. The spacers of EVE8 are a 550 bp lambda phage DNA (spacer 3) and an ARS sequence from yeast (spacer 4).

25

Nucleotide library (entry library)

A schematic illustration of the steps leading from expression steps to a nucleotide library are illustrated in figure 8.

30

Methods as well as suitable vectors and host cells for constructing and maintaining a library of nucleotide sequences in a cell are well known in the art. The primary requirement for the library is that it should be possible to store and amplify in it a number of primary vectors (constructs) according to this invention, the vectors

(constructs) comprising expressible nucleotide sequences from at least one expression state and wherein at least two vectors (constructs) are different.

5 One specific example of such a library is the well known and widely employed cDNA libraries. The advantage of the cDNA library is mainly that it contains only DNA sequences corresponding to transcribed messenger RNA in a cell. Suitable methods are also present to purify the isolated mRNA or the synthesised cDNA so that only substantially full-length cDNA is cloned into the library.

10 Methods for optimisation of the process to yield substantially full length cDNA may comprise size selection, e.g. electrophoresis, chromatography, precipitation or may comprise ways of increasing the likelihood of getting full length cDNAs, e.g. the SMART™ method (Clontech) or the CapTrap™ method (Stratagene).

15 Preferably the method for making the nucleotide library comprises obtaining a substantially full length cDNA population comprising a normalised representation of cDNA species. More preferably a substantially full length cDNA population comprises a normalised representation of cDNA species characteristic of a given expression state.

20 Normalisation reduces the redundancy of clones representing abundant mRNA species and increases the relative representation of clones from rare mRNA species.

25 Methods for normalisation of cDNA libraries are well known in the art. Reference may be given to suitable protocols for normalisation such as those described in US 5,763,239 (DIVERSA) and WO 95/08647 and WO 95/11986. and Bonaldo, Lennon, Soares, Genome Research 1996, 6:791-806; Ali, Holloway, Taylor, Plant Mol Biol Reporter, 2000, 18:123-132.

30 Enrichment methods are used to isolate clones representing mRNA which are characteristic of a particular expression state. A number of variations of the method broadly termed as subtractive hybridisation are known in the art. Reference may be given to Sive, John, Nucleic Acid Res, 1988, 16:10937; Diatchenko, Lau, Campbell
35 et al, PNAS, 1996, 93:6025-6030; Carninci, Shibata, Hayatsu, Genome Res, 2000,

10:1617-30, Bonaldo, Lennon, Soares, Genome Research 1996, 6:791-806; Ali, Holloway, Taylor, Plant Mol Biol Reporter, 2000, 18:123-132. For example, enrichment may be achieved by doing additional rounds of hybridization similar to normalization procedures, using e.g. cDNA from a library of abundant clones or
5 simply a library representing the uninduced state as a driver against a tester library from the induced state. Alternatively mRNA or PCR amplified cDNA derived from the expression state of choice can be used to subtract common sequences from a tester library. The choice of driver and tester population will depend on the nature of target expressible nucleotide sequences in each particular experiment.

10

Finally, enrichment may be achieved by subtractive hybridisation followed by colony picking.

15

In the library an expressible nucleotide sequence coding for one peptide is preferably found in different but similar vectors under the control of different promoters. Preferably the library comprises at least three primary vectors with an expressible nucleotide sequence coding for the same peptide under the control of three different promoters. More preferably the library comprises at least four primary vectors with an expressible nucleotide sequence coding for the same peptide under
20 the control of four different promoters. More preferably the library comprises at least five primary vectors with an expressible nucleotide sequence coding for the same peptide under the control of five different promoters, such as comprises at least six primary vectors with an expressible nucleotide sequence coding for the same peptide under the control of six different promoters, for example comprises at least
25 seven primary vectors with an expressible nucleotide sequence coding for the same peptide under the control of seven different promoters, for example comprises at least eight primary vectors with an expressible nucleotide sequence coding for the same peptide under the control of eight different promoters, such as comprises at least nine primary vectors with an expressible nucleotide sequence coding for the
30 same peptide under the control of nine different promoters, for example comprises at least ten primary vectors with an expressible nucleotide sequence coding for the same peptide under the control of ten different promoters.

The expressible nucleotide sequence coding for the same peptide preferably comprises essentially the same nucleotide sequence, more preferably the same nucleotide sequence.

- 5 By having a library with what may be termed one gene under the control of a number of different promoters in different vectors, it is possible to construct from the nucleotide library an array of combinations of genes and promoters. Preferably, one library comprises a complete or substantially complete combination such as a two dimensional array of genes and promoters, wherein substantially all genes are found
10 under the control of substantially all of a selected number of promoters.

According to another embodiment of the invention the nucleotide library comprises combinations of expressible nucleotide sequences combined in different vectors with different spacer sequences and/or different intron sequences. Thus any one
15 expressible nucleotide sequence may be combined in a two, three, four or five dimensional array with different promoters and/or different spacers and/or different introns and/or different terminators. The two, three, four or five dimensional array may be complete or incomplete, since not all combinations will have to be present.

20 The library may suitably be maintained in a host cell comprising prokaryotic cells or eukaryotic cells. Preferred prokaryotic host organisms may include but are not limited to *Escherichia coli*, *Bacillus subtilis*, *Streptomyces lividans*, *Streptomyces coelicolor* *Pseudomonas aeruginosa*, *Myxococcus xanthus*.

25 Yeast species such as *Saccharomyces cerevisiae* (budding yeast), *Schizosaccharomyces pombe* (fission yeast), *Pichia pastoris*, and *Hansenula polymorpha* (methylotropic yeasts) may also be used. Filamentous ascomycetes, such as *Neurospora crassa* and *Aspergillus nidulans* may also be used. Plant cells such as those derived from *Nicotiana* and *Arabidopsis* are preferred. Preferred
30 mammalian host cells include but are not limited to those derived from humans, monkeys and rodents, such as chinese hamster ovary (CHO) cells, NIH/3T3, COS, 293, VERO, HeLa etc (see Kriegler M. in "Gene Transfer and Expression: A Laboratory Manual", New York, Freeman & Co. 1990).

Concatemers

Fig. 9 shows a flow chart of the steps leading from an entry library comprising expressible nucleotide sequences to evolvable artificial chromosomes (EVAC) transformed into an appropriate host cell. Fig. 9a shows one way of producing the EVACs which includes concatenation, size selection and insertion into an artificial chromosome vector. Fig. 9b shows a one step procedure for concatenation and ligation of vector arms to obtain EVACs.

For the purposes of providing a method for assembling multiple expression cassettes ("cassettes") into a single host cell, and allowing their facile remixing between cells, the expression cassettes are assembled into concatemers.

A concatemer is a series of linked units. The concatemers according to the invention may comprise a selection of expressible nucleotide sequences from just one expression state and can thus be assembled from one library representing this expression state or it may comprise cassettes from a number of different expression states. The concatemers according to the invention are especially suitable for ligating into an artificial chromosome, which may be inserted into a host cell for coordinated expression. For this purpose, the variation among and between cassettes may be such as to minimise the chance of cross over as the host cell undergoes cell division such as through minimising the level of repeat sequences occurring in any one concatemer, since it is not an object of this embodiment of the invention to obtain recombination of concatemers with a segment in the host genome or an epitope of the host cells nor is it an object to obtain intra- or extra concatemeric recombination.

According to a preferred embodiment of the invention the concatemer comprises at least a first cassette and a second cassette, said first cassette being different from said second cassette. More preferably, the concatemer comprises cassettes, wherein substantially all cassettes are different. The difference between the cassettes may arise from differences between promoters, and/or expressible nucleotide sequences, and/or spacers, and/or introns and/or terminators.

The number of cassettes in a single concatemer is largely determined by the host species into which the concatemer is eventually to be inserted and the vector through which the insertion is carried out. The concatemer thus may comprise at least 10 cassettes, such as at least 15, for example at least 20, such as at least 25, for example at least 30, such as from 30 to 60 or more than 60, such as at least 75, for example at least 100, such as at least 200, for example at least 500, such as at least 750, for example at least 1000, such as at least 1500, for example at least 2000 cassettes.

Each of the cassettes may be laid out as described above.

Thus, in a preferred embodiment a concatemer is used to denote a number of serially linked nucleotide cassettes, wherein at least two of the serially linked nucleotide units comprises a cassette having the basic structure

[rs₂-SP-PR-X-TR-SP-rs₁]

wherein

rs₁ and rs₂ together denote a restriction site,

SP denotes a spacer of at least two nucleotide bases,

PR denotes a promoter, capable of functioning in a host cell,

X denotes an expressible nucleotide sequence,

TR denotes a terminator, and

SP denotes a spacer of at least two nucleotide bases.

wherein the variables of the cassette have the meaning as defined elsewhere in this specification. Optionally the cassettes comprise an intron sequence between the promoter and the expressible nucleotide sequence and/or between the terminator and the expressible nucleotide sequence as discussed above.

According to one aspect of the invention, a concatemer comprises cassettes with expressible nucleotide from different expression states, so that non-naturally occurring combinations or non-native combinations of expressible nucleotide sequences are obtained.

According to a preferred embodiment of the invention the concatemer comprises at least a first cassette and a second cassette, said first cassette being different from

said second cassette. More preferably, the concatemer comprises cassettes, wherein substantially all cassettes are different. The difference between the cassettes may arise from differences between promoters, and/or expressible nucleotide sequences, and/or spacers, and/or terminators, and/or introns.

5

The concatenation may be carried out in different ways.

10

Cassettes to be concatenated are normally excised from a vector or they are synthesised through PCR. After excision the cassettes may be separated from the vector through size fractionation such as gel filtration or through tagging of known sequences in the cassettes. The isolated cassettes may then be ligated together either through interaction between sticky ends or through ligation of blunt ends.

15

More preferably the cassettes may be concatenated without an intervening purification step through excision from a vector with two restriction enzymes, one leaving sticky ends on the cassettes and the other one leaving blunt ends in the vectors.

20

An alternative way of producing concatemers free of vector sequences would be to PCR amplify the cassettes from a single stranded primary vector. The PCR product must include the restriction sites RS2 and RS2' which are subsequently cleaved by its cognate enzyme(s). Concatenation can then be performed using the digested PCR product, essentially without interference from the single stranded primary vector template or the small double stranded fragments, which have been cut from the ends.

25

30

When the vectors comprising the cassettes are single stranded, the cassettes may be excised and be made double stranded through PCR techniques, which only prime the cassette sequence and not the vector sequence. Sticky ends can be made by cleaving with a restriction enzyme leaving sticky ends and the cassettes can be assembled without interaction from the single stranded vector fragments.

The concatemer may be assembled or concatenated by concatenation of at least two cassettes of nucleotide sequences each cassette comprising a first sticky end, a

spacer sequence, a promoter, an expressible nucleotide sequence, a terminator, and a second sticky end.

After concatenation has been completed, concatemers of the desired size may be selected through size selection, such as selection for concatemers having at least 10 cassettes, such as at least 15, for example at least 20, such as at least 25, for example at least 30, such as from 30 to 60 or more than 60, such as at least 75, for example at least 100, such as at least 200, for example at least 500, such as at least 750, for example at least 1000, such as at least 1500, for example at least 2000 cassettes. The number of cassettes in each concatemer may be controlled by size fractionation after concatenation, since the size of the concatemers is approximately proportional to the number of cassettes.

Preferably at least one inserted concatemer in each cell comprises at least one selectable marker. Selectable markers generally provide a means to select, for growth, only those cells which contain a vector. The selectable markers are inserted into the concatemers to complement one or more mutations in a central biosynthetic pathway, these mutations being inserted into the host cells. Such markers are of two types: drug resistance and auxotrophic. A drug resistance marker enables cells to detoxify an exogenously added drug that would otherwise kill the cell. Auxotrophic markers allow cells grow in media lacking an essential component by enabling cells to synthesise the essential component (usually an amino acid).

Illustrative and non-limiting examples of common selectable markers with a brief description of their mode of action follow:

Prokaryotic

- Ampicillin: interferes with a terminal reaction in bacterial cell wall synthesis. The resistance gene (bla) encodes beta-lactamase which cleaves the beta-lactam ring of the antibiotic thus detoxifying it.
- Tetracycline: prevents bacterial protein synthesis by binding to the 30S ribosomal subunit. The resistance gene (tet) specifies a protein that modifies the bacterial membrane and prevents transport of the antibiotic into the cell.
- Kanamycin: binds to the 70S ribosomes and causes misreading of messenger RNA. The resistant gene (nptH) modifies the antibiotic and prevents interaction with the ribosome.
- Streptomycin: binds to the 30S ribosomal subunit, causing misreading of messenger RNA. The resistance gene (Sm) modifies the antibiotic and prevents interaction with the ribosome.
- Zeocin: this new bleomycin-family antibiotic intercalates into the DNA and cleaves it. The Zeocin resistance gene encodes a 13,665 dalton protein. This protein confers resistance to Zeocin by binding to

the antibiotic and preventing it from binding DNA. Zeocin is effective on most aerobic cells and can be used for selection in mammalian cell lines, yeast, and bacteria.

- Auxotrophic markers.

Eukaryotic

- 5
 - Hygromycin: a aminocyclitol that inhibits protein synthesis by disrupting ribosome translocation and promoting mistranslation. The resistance gene (hph) detoxifies hygromycin -B- phosphorylation.
 - Histidinol: cytotoxic to mammalian cells by inhibiting histidyl-tRNA synthesis in histidine free media. The resistance gene (hisD) product inactivates histidinol toxicity by converting it to the essential amino acid, histidine.
- 10
 - Neomycin (G418): blocks protein synthesis by interfering with ribosomal functions. The resistance gene ADH encodes amino glycoside phosphotransferase which detoxifies G418.
 - Uracil: Laboratory yeast strains carrying a mutated gene which encodes orotidine -5'- phosphate decarboxylase, an enzyme essential for uracil biosynthesis, are unable to grow in the absence of exogenous uracil. A copy of the wild-type gene (ura4+, *S. pombe* or URA3 *S. cerevisiae*) carried on the vector will complement this defect in transformed cells.
- 15
 - Adenosine: Laboratory strains carrying a deficiency in adenosine synthesis maybe complemented by a vector carrying the wild type gene, ADE 2.
 - Amino acids: Vectors carrying the wild-type genes for LEU2, TRP 1, HIS 3 or LYS 2 may be used to complement strains of yeast deficient in these genes.
- 20
 - Zeocin: this new bleomycin-family antibiotic intercalates into the DNA and cleaves it. The Zeocin resistance gene encodes a 13,665 dalton protein. This protein confers resistance to Zeocin by binding to the antibiotic and preventing it from binding DNA. Zeocin is effective on most aerobic cells and can be used for selection in mammalian cell lines, yeast, and bacteria.

- 25 The number of concatemers in one single cell may be at least one concatemer per cell, preferably at least 2 concatemers per cell, more preferably 3 per cell, such as 4 per cell, more preferably 5 per cell, such as at least 5 per cell, for example at least 6 per cell, such as 7, 8, 9 or 10 per cell, for example more than 10 per cell. As described above, each concatemer may preferably comprise up to 1000 cassettes,
- 30 and it is envisaged that one concatemer may comprise up to 2000 cassettes. By inserting up to 10 concatemers into one single cell, this cell may thus be enriched with up to 20,000 new expressible genes, which under suitable conditions may be turned on and off by regulation of the regulatable promoters. However it may be more preferable to provide cells having anywhere between 10 and 1000 novel
- 35 genes, such as 20-900 novel genes, for example 30 to 800 novel genes, such as 40 to 700 novel genes, for example 50 to 600 novel genes, such as from 60 to 300 novel genes. The genes may advantageously be located on 1 to 10 such as from 2 to 5 different concatemers in the cells. Each concatemer may advantageously comprise from 10 to 1000 genes, such as from 10 to 750 genes, such as from 10 to
- 40 500 genes, such as from 10 to 200 genes, such as from 20 to 100 genes, for example from 30 to 60 genes.

The concatemers may be inserted into the host cells according to any known transformation technique, preferably according to such transformation techniques that ensure stable and not transient transformation of the host cell. The concatemers may thus be inserted as an artificial chromosome which is replicated by the cells as they divide or they may be inserted into the chromosomes of the host cell. The concatemer may also be inserted in the form of a plasmid such as a plasmid vector, a phage vector, a viral vector, a cosmid vector, that is replicated by the cells as they divide. Any combination of the three insertion methods is also possible. One or more concatemers may thus be integrated into the chromosome(s) of the host cell and one or more concatemers may be inserted as plasmids or artificial chromosomes. One or more concatemers may be inserted as artificial chromosomes and one or more may be inserted into the same cell via a plasmid.

The basic requirements for a functional artificial chromosome have been described in US 4,464,472, the contents of which is hereby incorporated by reference. An artificial chromosome or a functional minichromosome, as it may also be termed must comprise a DNA sequence capable of replication and stable mitotic maintenance in a host cell comprising a DNA segment coding for centromere-like activity during mitosis of said host and a DNA sequence coding for a replication site recognized by said host.

Suitable artificial chromosomes include a Yeast Artificial Chromosome (YAC) (see e.g. Murray et al, Nature 305:189-193; or US 4,464,472), a mega Yeast Artificial Chromosome (mega YAC), a Bacterial Artificial Chromosome (BAC), a mouse artificial chromosome, a Mammalian Artificial Chromosome (MAC) (see e.g. US 6,133,503 or US 6,077,697), an Insect Artificial Chromosome (BUGAC), an Avian Artificial Chromosome (AVAC), a Bacteriophage Artificial Chromosome, a Baculovirus Artificial Chromosome, a plant artificial chromosome (US 5,270,201), a BIBAC vector (US 5,977,439) or a Human Artificial Chromosome (HAC).

The artificial chromosome is preferably so large that the host cell perceives it as a "real" chromosome and maintains it and transmits it as a chromosome. For yeast and other suitable host species, this will often correspond approximately to the size

of the smallest native chromosome in the species. For *Saccharomyces*, the smallest chromosome has a size of 225 Kb.

5 MACs may be used to construct artificial chromosomes from other species, such as insect and fish species. The artificial chromosomes preferably are fully functional stable chromosomes. Two types of artificial chromosomes may be used. One type, referred to as SATACs [satellite artificial chromosomes] are stable heterochromatic chromosomes, and the other type are minichromosomes based on amplification of euchromatin.

10

Mammalian artificial chromosomes provide extra-genomic specific integration sites for introduction of genes encoding proteins of interest and permit megabase size DNA integration, such as integration of concatemers according to the invention.

15 According to another embodiment of the invention, the concatemer may be integrated into the host chromosomes or cloned into other types of vectors, such as a plasmid vector, a phage vector, a viral vector or a cosmid vector.

20 A preferable artificial chromosome vector is one that is capable of being conditionally amplified in the host cell, e.g. in yeast. The amplification preferably is at least a 10 fold amplification. Furthermore, it is advantageous that the cloning site of the artificial chromosome vector can be modified to comprise the same restriction site as the one bordering the cassettes described above, i.e. RS2 and/or RS2'.

25 It is also conceivable that recombination can be used to generate concatemers, e.g. through the modification of techniques like the Creator system (Clontech) which uses the Cre-loxP mechanism (ref: Sauer B 1993 Methods Enzymol 225:890-900) to directionally join DNA molecules by recombination or like the Gateway system (Life Technologies, US 5,888,732) using lambda *att* attachment sites for directional recombination (Landy A 1989, Ann Rev Biochem 58:913). It is envisaged that also
30 lambda *cos* site dependent systems can be developed to allow concatenation.

The concatemer may be assembled or concatenated by concatenation of at least two cassettes of nucleotide sequences each cassette comprising a first sticky end, a

spacer sequence, a promoter, an expressible nucleotide sequence, a terminator, and a second sticky end. A flow chart of the procedure is shown in figure 9a.

Preferably concatenation further comprises

- 5 starting from a primary vector [RS1-RS2-SP-PR-X-TR-SP-RS2'-RS1'],
 wherein X denotes an expressible nucleotide sequence,
 RS1 and RS1' denote restriction sites,
 RS2 and RS2' denote restriction sites different from RS1 and RS1',
 SP denotes a spacer sequence of at least two nucleotides,
10 PR denotes a promoter,
 TR denotes a terminator,
 i) cutting the primary vector with the aid of at least one restriction
 enzyme specific for RS2 and RS2' obtaining cassettes having the
 general formula [rs₂-SP-PR-X-TR-SP-rs₁] wherein rs₁ and rs₂ together
15 denote a functional restriction site RS2 or RS2',
 ii) assembling the cut out cassettes through interaction between rs₁ and
 rs₂.

20 According to an especially preferred embodiment, vector arms each having a RS2
 or RS2' in one end and a non-complementary overhang or a blunt end in the other
 end are added to the concatenation mixture together with the cassettes described
 above to further simplify the procedure (see Fig. 9b). One example of a suitable
 vector for providing vector arms is disclosed in Fig. 15 TRP1, URA3, and HIS3 are
 auxotrophic marker genes, and AmpR is an antibiotic marker gene. CEN4 is a
25 centromer and TEL are telomeres. ARS1 and PMB1 allow replication in yeast and E.
 coli respectively. BamH I and Asc I are restriction enzyme recognition sites. The
 nucleotide sequence of the vector is set forth in SEQ ID NO 4. The vector is
 digested with BamHI and AscI to liberate the vector arms, which are used for ligation
 to the concatemer.

30

 The general concatenation strategy is illustrated in Figure 16. The ratio of vector
 arms to cassettes determines the maximum number of cassettes in the concatemer
 as illustrated in figure 17. The vector arms preferably are artificial chromosome
 vector arms such as those described in Fig. 15.

35

It is of course also possible to add stopper fragments to the concatenation solution, the stopper fragments each having a RS2 or RS2' in one end and a non-complementary overhang or a blunt end in the other end. The ratio of stopper fragments to cassettes can likewise control the maximum size of the concatemer.

5

As an alternative to providing vector arms for the concatenation procedure is possible to ligate the concatemer into an artificial chromosome selected from the group comprising yeast artificial chromosome, mega yeast artificial chromosome, bacterial artificial chromosome, mouse artificial chromosome, human artificial chromosome.

10

The number of concatemers in one single cell may be at least one concatemer per cell, preferably at least 2 concatemers per cell, more preferably 3 per cell, such as 4 per cell, more preferably 5 per cell, such as at least 5 per cell, for example at least 6 per cell, such as 7, 8, 9 or 10 per cell, for example more than 10 per cell. As described above, each concatemer may preferably comprise up to 1000 cassettes, and it is envisaged that one concatemer may comprise up to 2000 cassettes. By inserting up to 10 concatemers into one single cell, this cell may thus be enriched with up to 20,000 heterologous expressible genes, which under suitable conditions may be turned on and off by regulation of the regulatable promoters.

15

20

Often it is more preferable to provide cells having anywhere between 10 and 1000 heterologous genes, such as 20-900 heterologous genes, for example 30 to 800 heterologous genes, such as 40 to 700 heterologous genes, for example 50 to 600 heterologous genes, such as from 60 to 300 heterologous genes or from 100 to 400 heterologous genes which are inserted as 2 to 4 artificial chromosomes each containing one concatemer of genes. The genes may advantageously be located on 1 to 10 such as from 2 to 5 different concatemers in the cells. Each concatemer may advantageously comprise from 10 to 200 genes, such as from 20 to 100 genes, for example from 30 to 60 genes, or from 50 to 100 genes.

25

30

EXAMPLES OF MULTIPLE PARAMETER SCREENS

Example 1: Multiple Parameter Screen for ligand activators of RAR β and P450s metabolism

35

A yeast strain expressing the P450's CYP3A4 α , CYP2C9, CYP2D6, RAR β and containing a retinoic acid (RA) responsive promoter driving the transcription of the HIS3 marker is mated with a producer yeast strain (comprising a population of cells each containing a set of heterologous expression cassettes located on artificial chromosomes). When the diploids are plated on HIS selective media, only cells that produce RAR activators will survive. All construct assembly and handling done according to standard procedures described in Current protocols in molecular biology 1999, John Wiley & Sons, Inc.

Example 2: Multiple Parameter Screen for P450s metabolism and ligands that activate RAR β but not RAR α

The same diploid yeast cells as in example 1 except that the reporter gene for RAR β is GFP (Green Fluorescent Protein) are co-gel-encapsulated with another yeast cell line that expresses RAR α and contains a RA responsive promoter driving the transcription of YFP (Yellow Fluorescent Protein). The gel encapsulation is done as in Sahar et al., 1994., Flow cytometric analysis of entire microbial colonies. Cytometry 15: 213-221. The gel particles are then sorted for high Green Fluorescence intensity and low Yellow Fluorescence intensity.

Example 3: Multiple Parameter Screen for P450 metabolism and ligands that activate RAR β but not RAR α or RAR γ

The same gel particles as in example 2 are double encapsulated with a yeast cell line that expresses RAR γ and contains a RA responsive promoter driving the transcription of CFP (Cyan Fluorescent Protein). The double gel encapsulation is done in principal as in Gift et al., 1996, Nature Biotechnology, Vol. 14, 884-887. The gel particles are then sorted for high green fluorescence intensity and low yellow and cyan fluorescence intensities.

Example 4: Multiple Parameter Screen for P450 metabolism and ligands that activate PPAR γ and PPAR α in a mammalian system

A producer yeast strain comprising a population of cells each containing a set of heterologous expression cassettes located on artificial chromosomes and expressing the P450s, CYP3A4 α and CYP2C, is co-gel-encapsulated with a mammalian cell line expressing PPAR γ , PPAR α , and containing a PPAR γ responsive promoter driving the transcription of YFP and a PPAR α responsive promoter driving the transcription of CFP. Handling and manipulation of mammalian cells done according to standard procedures described in Current protocols in molecular biology 1999, John Wiley & Sons, Inc. The gel particles are sorted for high yellow and cyan fluorescence intensity.

Example 5: Multiple Parameter Screen for multi-drug resistant S. aureus (MRSA) growth inhibition and DNA Polymerase III inhibition

The producer strains (comprising a population of cells each containing a set of heterologous expression cassettes located on artificial chromosomes) are gel encapsulated using conditions that give on average one strain per bead as described in US 4,399,219. The beads are placed under conditions that allow the producer strains to grow and the heterologous genes to be expressed. The beads are double encapsulated with a MRSA strain and in the presence of a substrate of DNA polymerase III that when metabolised produces fluorescent molecules. Gel droplets that have small or no MRSA colonies and which are not fluorescent are selected.

Example 6A: Multiple Parameter Screen for DNA Topoisomerase II inhibition and growth inhibition of HeLa cells

The producer strains (comprising a population of cells each containing a set of heterologous expression cassettes located on artificial chromosomes) in a media containing a stain that binds to DNA double strand breaks are plated. HeLa cells are plated over the producer strains. Producer strains in areas where cancer cell growth was inhibited and which are coloured are selected. See figure 3B

Example 6B: Multiple Parameter Screen for specific DNA Topoisomerase II poisons

The producer strains (comprising a population of cells each containing a set of heterologous expression cassettes located on artificial chromosomes) are gel encapsulated using conditions that give on average one strain per bead as described in US 4,399,219. The beads are placed under conditions that allow the producer strains to grow and the heterologous genes to be expressed. The beads are double gel encapsulated with yeast cells bearing the topoisomerase II mutant top2-1 (like JN394t2-1), expressing GFP and yeast cells deleted for yeast topoisomerase I (like JN394t1), expressing DsRed. The beads are sorted for green and red fluorescence on a FACS. Beads with do not produce red or green fluorescence produce produced topoisomerase I specific poisons. Beads producing only green fluorescent have topoisomerase II specific poisons. The reporter strains described are based on the strains described in Methods In molecular biology, 95, 315-327. See figure 3B.

EXAMPLES OF OPTIMISATION PROCESSES USING THE CURRENT EVOLUTIONARY APPROACHES

Examples of how the current invention can be used to evolve cells with potential pharmaceutical, industrial, agronomic, or nutritional utility are now provided.

Evolution of specific structural classes via short to medium sized pathways

Example 7: Evolution of Carotenoid like compounds

UTILITY

Carotenoids are natural pigments displaying yellow, orange, pink, red and blue colours. A major role is protection against oxidative damage. Carotenoids are both pharmaceutically relevant (used to treat bronchial asthma and involved in the prevention of cancer) and of commercial value.

SCREENING & SELECTION STRATEGY

- Production of a different colour by host cell. Screen done manually by plating and picking
- Anti-oxidant protection. Screen done using methylene blue as a producer of singlet oxygen species.

PROCEDURE

- 5 STEP 1 Essentially full length cDNA is made from the species in the list provided in this example.
- 10 STEP 2 cDNA libraries are made using a pool of 4 entry vectors: pEVE4, pEVE5, pEVE8 and pEVE9 in a proportion of 30:30:1:30. See Figures 11, 12, 13, and 14.
- 15 STEP 3 Each cDNA library is normalised essentially as method 4 described in Bonaldo, MF et al. (1996) Genome Res. 6: 791-806.
- 20 STEP 4 Coding sequences from a non-normalised yeast (*Saccharomyces cerevisiae*) cDNA library are amplified by PCR and are used as driver for subtractive hybridization against single stranded circular DNA prepared from the normalized library produced in step 3, in order to remove household genes. Remaining single stranded circles are purified, converted to double stranded DNA and used to transform E.coli.
- 25 STEP 5 EVAC (Evolvable Artificial Chromosome) containing cell populations are made using 10 different normalised and enriched cDNA libraries in each.
- 30 **Preparation of expression cassettes**
1. inoculate 5 ml of LB-medium (Sigma) containing 100 µg/L ampicillin with library inoculum corresponding to a 10+ fold representation of library. Grow overnight.
 2. make plasmid miniprep from 1.5 ml of culture (E.g. Qiaprep spin miniprep kit)
 3. digest plasmid w. Srf 1
 4. dephosphorylate fragments and heat inactivate phosphatase(20 min, 80°C)
 5. digest w. Asc1
 6. run 1/10 of reaction in 1% agarose gel to estimate amount of fragment
- Preparation of pYAC4-Asc arms**
- 35 1. inoculate 150 ml of LB medium (Sigma) with a single colony of DH5α containing pYAC4-AscI
 2. grow to OD₆₀₀ ~ 1, harvest cells and make plasmid preparation
 3. digest 100µg pYAC4-AscI w. BamH1 and Asc1

113

4. dephosphorylate fragments and heat inactivate phosphatase(20 min, 80°C)
5. purify fragments(e.g. Qiaquick Gel Extraction Kit)
6. run 1 % agarose gel to estimate amount of fragment

Preparation of EVACs

- 5 1. mix expression cassette fragments with YAC-arms so that cassette/arm ration is ~1000/1
2. if needed concentrate mixture (use e.g. Microcon YM30) so fragment concentration > 75 ng/μL of reaction
- 10 3. add 1 U T4 DNA ligase, incubate 16°C, 1-3 h . Stop reaction by adding 1 μL of 500 mM EDTA
4. run pulsed field gel (CHEF III, 1% LMP agarose, ½ strength TBE, angle 120, temperature 12 C, voltage 5.6V/cm, switch time ramping 5 – 25 s, run time 30 h) Load sample in 2 lanes.
5. Stain part of the gel that contains molecular weight markers
- 15 6. cut sample lanes corresponding to MW. 100 – 500 kb
7. agarose gel in high NaCL agarase buffer . 1 u agarase / 100 mg gel
8. concentrate preparation to < 20 μL
9. transform suitable yeast strain w. preparation using electroporation:
100 ml of YPD is inoculated with one yeast colony and grown to $OD_{600} \cong 1.3$ to 1.5.
- 20 The culture is harvested by centrifuging at $4000 \times g$ and 4°C. The cells are re-suspended in 16 ml sterile H₂O. Add 2 ml 10 × TE buffer, pH 7.5 and swirl to mix. Add 2 ml 10 × lithium acetate solution (1 M, pH 7.5) and swirl to mix. Shake gently 45 min at 30°C. Add 1.0 ml 0.5 M DTE while swirling. Shake gently 15 min at 30°C. The yeast suspension is diluted to 100 ml with sterile water. The cells are washed and concentrated by centrifuging at $4000 \times g$, resuspending the pellet in 50 ml ice-cold sterile water, centrifuging at $4000 \times g$, resuspending the pellet in 5 ml ice-cold sterile water, centrifuging at $4000 \times g$ and resuspending the pellet in 0.1 ml ice-cold sterile 1 M sorbitol. The electroporation was done using a *Bio-Rad Gene Pulser*. In a sterile 1.5-ml microcentrifuge tube 40 μl concentrated yeast cells were mixed with 5 μl 1:10 diluted EVAC preparation. The yeast-DNA mix is transferred to an ice-cold 0.2-cm-gap disposable electroporation cuvette and pulsed at 1.5 kV, 25 μF, 200 Ω. 1 ml ice-cold 1 M sorbitol is added to the cuvette to recover the yeast. Aliquots are spread on selective plates containing 1 M sorbitol. Incubate at 30°C until colonies appear.
- 25
- 30
- 35 STEP 6 The EVAC containing cell libraries produced in step 5) are pooled into one screening population.
- STEP 7 The screening population is divided into two equal portions. One of the portions is screened for anti-oxidant properties (step 8) and the
- 40 other for differential colour production (step 9).

STEP 8 Anti-oxidant screen:

- a. The screening population is amplified ten times and divided in 10 portions.
- 5 b. The sub populations are grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- c. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ and the cells are incubated under inducing conditions for 24 hours
10 prior to screening.
- d. Each sub population is exposed to 1 out of a range of 5 concentrations of Methylene blue. Immediately after exposure to Methylene blue, the cells are irradiated with a 200 W halogen lamp for 2 hours.
- 15 e. Aliquots of each population re plated in different dilutions and remaining population stored,
- f. Survival rates are determined after 48 hours. The surviving cell population exposed to the highest concentration of Methylene blue, where cells statistically representing 10% of the parent cell lines
20 survived, is selected.

STEP 9 Differential colour production screen:

- a. The screening population is grown on plates under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- 25 b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ for 24 hours prior to screening.
- c. Coloured cells are selected.
- d. The cells representing (by statistics) the 10% strongest colour
30 expressing cell lines are selected.

Remixing of genetic diversity selected in steps 8 and 9 is done by excising the expression cassettes, mixing them and religating into new EVACs. This process is described in steps 10 to 13:

115

- STEP 10 Each of the populations selected in steps 8 and 9 is amplified and equal amounts of each amplified population are pooled.
- 5 STEP 11 Total DNA is isolated following standard procedures.
- STEP 12 The total DNA is digested with *Ascl* and DNA fragments of the appropriate size (2-10kB) are isolated.
- 10 STEP 13 New EVACs containing the purified DNA fragments and 10% of cassettes (w/w) that have not been used to assemble EVACs in any previous synthesis are synthesised essentially as described in step 5.
- STEP 14 Steps 7 to 13 are repeated 5 times always taking forward the best 10% of cell lines from each screen.
- 15 STEP 15 The new cell population resulting from the completion of the fifth cycle is not divided and is grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 μ M Cu₂SO₄.
- 20 STEP 16 The combined population is now screened for colour and anti-oxidant activity simultaneously. The concentration of Methylene blue used is the highest concentration where, after 2 hours of exposure to the methylene blue, the number of surviving coloured cells represents 5% of the cell lines in the original population. Cells that survive this concentration of MB and are coloured are selected.
- 25 STEP 17 The selected population is amplified and new EVACs are produced as described in steps 11 to 13.
- 30 STEP 18 Steps 15 to 17 are repeated 30 times always taking forward cells representing the best 5% of cell lines.

5 STEP 19 Cell lines that can survive a 10X higher concentration of Methylene blue than the original population and have clearly visible bright yellow to red colours are taken out of the evolution process. The genes responsible for these activities are subcloned and characterised by DNA sequencing.

10 STEP 20 Cells with the characteristics described in step 19 and that have significantly different genotypes are analysed using standard natural product chemistry in order to identify the compound(s) responsible for the phenotype.

PRIORITISED SPECIES AND TAXONOMIC GROUPS

Sourced species are divided into:

- 15 • Species that produce carotenoids: plants, algae, some fungi and photosynthetic bacteria
- Species that modify carotenoids to produce other carotenoids: some animals
- Specific genes

Species that produce carotenoids:

20 Plants: *Actinidia deliciosa* (Kiwi); *Arabidopsis thaliana*; *Brassica rapa*, *Tagetes erecta* (Marigold flowers), *Olea europaea* (olive), *Lactuca sativa* var. *romaine* (romaine lettuce), *Quercus robur* (oak), *Pinus pinaster* (maritime pine), *Capsicum annuum* (Pepper), *Bixa orellana*, *Sarcina lutea*, *Viola tricolor*, *Lonicera japonica*, *Delonix regia*, *Zea mays* (maize), *Eschscholzia californica*, *Carica papaya* (papaya),
 25 *Daucus carota* (carrot), *Lycopersicon esculentum* (tomato), *Crocus sativus* (saffron), *Verbascum phlomoides*, *Physalis alkekengi*, *Gentiana* spp., *Nicotiana tabacum*, *Pittosporum tobira*
Algae: *Rhizophora mangle* (red mangrove), *Haematococcus pluvialis* (Green Algae),
 30 *Enteromorpha linza* (Patagonian macroalga), *Ulva lactuca* (Sea lettuce), *Caulerpa mexicana*, *Gigartina* sp, *Polysiphonia* sp, *Porphyra* sp, *Macrocystis pyrifera* (Giant kelp), *Sargassum* sp., *Nanochlorum eucaryotum*, *Dunaliella bardawil*, *Scenedesmus obliquus*, *Oscillatoria rubescens*, *Phormidium luridum*, *Arthrospira* spp., *Astasia ocellata*, *Fucus vesiculosus*, *Bathycoccus prasinos*, *Micromonas pusilla*, *Botryococcus braunii*,

Fungi: *Xanthophyllomyces dendrorhous*, *Neurospora crassa*, *Cantharellus cibarius*, *Phycomyces blakesleeanus*, *Puccinia graminis*, *Epicoccum* spp., *Lycogola epidendron*

5 Bacteria: *Roseiflexus castenholzii*, *Streptococcus faecium*, *Rhodopseudomonas acidophila*, *Erwinia herbicola*, *Agrobacterium aurantiacum*, *Halorhodospira abdelmalekii*, *Halorhodospira halochloris*, *Anabaena PCC 7120*, *Chlorobium tepidum*, *Chloroflexus aurantiacus*, *Thermus thermophilus*, *flexibacter* spp., *Rhodobacter capsulatus*, *Staphylococcus aureus*, *Deinococcus radiodurans*, *Meiothermus ruber*, *Chloroflexus aurantiacus*

10

Species that modify carotenoids:

Birds: *Carduelis tristis*, *Cardinalis cardinalis*, flamingo

Fishes: *Carassius auratus* (goldfish), *Micropterus salmoides* (black bass), *Paracheirodon axelrodi* (cardinal tetra), *Amphiprion ocellaris* (common clown),
15 *Zebrasoma flavescens* (Yellow tang), *Synchiropus splendidus* (mandarinfish), *Lactoria cornuta* (long-horned cowfish)

Invertebrates: *Cucumaria japonica* (sea cucumber), *Ianthella basta* (sponge), *Clibanarius erythropus* (hermit crab), *Daphnia magna*, *Homarus americanus* (Lobster), *Paralithodes brevipes* (King Crab), *Fusinus perplexus* (seashell),
20 *Halichondria okadai* (sponge), *Suberites massa* (sponge), *Pentacta australis* (sea cucumber), *Pseudocentrotus depressus*, (sea urchin), *Ophiuroida* spp. (brittle star), *Papilio xuthus* (butterfly), *Mytilus coruscus* (japanese sea mussel), *Crassostrea gigas* (oyster), *Glossodoris* spp., (sea slug), *Fromia elegans* (star fish), *Actinia equina* (strawberry beadlet anemone), *Anemonia viridis* (anemone), *Hippolytina*
25 *grahami*, (shrimp), *Lysmata debelius* (shrimp), *Halocynthia papillosa* (sea squirt), *Crossaster papposus* (starfish)

Specific Carotenoid genes :

ggps, psy, pds, zds, lcy-b, lcy-e, bhy, zep (*Gentiana* sp.), idi, crtC, crtF
30 (*Rhodobacter capsulatus*), crtE, crtB, crtI, crtY, crtZ (*Erwinia uredovora*), zds (*Nostoc anabaena*), pds (*Synechococcus PCC7942*), crtE, crtB, crtI, crtY, crtZ (*Erwinia herbicola*), crtM, crtN (*Staphylococcus aureus*), crtI, crtYb (*Xanthophyllomyces dendrorhous*), ccs, crtL (*Capsicum annuum*), crtL, bchy (*Nicotiana tabacum*), lcy-b, lcy-e (*Prochlorococcus* sp.), idi (*Saccharomyces*

cerevisiae), crtI, crtYe, crtYf, crtEb (*Corynebacterium sp.*), psy-1 (*Lycopersicon esculentum*), al1 (*Neurospora crassa*)

Example 8: Evolution of Omega fatty acid like compounds

5

UTILITY

Unsaturated fatty acids are important components for normal cellular function, are involved in cell membrane fluidity and serve as precursors to eicosanoids, including prostaglandins and leukotrienes. In mammals, these eicosanoids are involved in inflammatory responses, regulation of blood pressure, and reproductive function

SCREENING & SELECTION STRATEGY

- Cell membrane fluidity (Flow cytometry screen)
- Tolerance to cold (growth assay)

15

PROCEDURE.

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

- | | | |
|----|--------|---|
| 20 | Step 7 | The screening population is divided into 2 equal portions. One of the portions is screened for tolerance to cold (step 8) and the other for cell membrane fluidity (step 9) |
| 25 | Step 8 | Tolerance to cold: |
| 30 | | a. The screening population is amplified ten times and divided in 10 portions. |
| | | b. The sub populations are grown in liquid culture under selective conditions for the artificial chromosomes to an OD ₆₀₀ of 0.6 – 1.0. |
| | | c. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu ₂ SO ₄ and the cells are grown under inducing conditions for 24 hours prior to screening. |
| 35 | | d. Each sub population is plated and grown at temperatures ranging from 10 to 30°C. Cold tolerance is determined when the first colonies appear on a given plate (at a given temperature). The cell population |

growing at the lowest temperature after a predetermined period of time where cells statistically representing 10% of the original cell lines grow within the same defined period of time, is selected.

- 5 Step 9 Cell membrane fluidity screen:
- a. The screening population is grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- 10 b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄. The cells are grown under inducing conditions for 20 hours with 1 tenth of the library being analysed by flow cytometry after every 2 hours.
- 15 c. For each of the sub populations flow cytometry is used to isolate the 10 % of cell lines with the most fluid cell membranes but which are still growing normally. This is done essentially as described in Benderitter M. et al, Cytometry, 2000, 39(2), 151-7
- 20 Step 10 Each of the populations selected in steps 8) and 9) is amplified. For each of the selected populations, steps 11-13 are repeated separately.
- 25 Step 16 The combined population is now screened for ethanol resistance and increased membrane fluidity. The concentration of ethanol used is the highest concentration where, after overnight exposure to ethanol, the number of surviving cells whose membrane fluidity exceeds the average fluidity by more than 2 x the standard deviation at 30 °C represents 5% of the cell lines in the original population.
- 30 Step 19 Cells that can survive a 1.5 x higher concentration of Ethanol than the original population and have a cell membrane fluidity that exceeds the average fluidity of the original population by more than 5 x the standard deviation at 30 °C are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing.

PRIORITISED SPECIES AND TAXONOMIC GROUPS

- Plants (in particular seeds)
- Animals (in particular adipose tissues)
- Fish
- 5 • Random group of taxonomically diverse eukaryotic species

Evolution of specific structural classes via longer pathways**Example 9: Evolution of Retinoid like compounds**

10

UTILITY:

Retinoids are derivatives of vitamin A and are modulators of cellular proliferation as well as effectors of morphogenic changes. Activity of retinoids as antineoplastic agents has been demonstrated in several *in vivo* experimental carcinogen models (mainly for skin, respiratory tract, urinary bladder, breast, digestive tract) Cellular responses to retinoids are generally mediated by two families of nuclear receptors (RARs and RXRs) that belong to the steroid-thyroid hormone (or nuclear) receptor superfamily and behave as ligand-activated transcription factors that bind as dimers to the *cis*-acting response elements of target genes.

20

Different retinoic acid receptor isotypes display a characteristic pattern of tissue distribution, RAR α being the most ubiquitously distributed. RAR β plays an important role in lung development and has been proposed to have a tumour suppressor function in lung.

25

SCREENING & SELECTION STRATEGY

- To obtain carotenoid like compounds screens for colour production and anti-oxidant protection are used (see example 7).
- To obtain retinoid like compounds an activation assay of retinoic acid receptor, RAR β is used. This assay employs a reporter system. Reporter construct is initially placed intra-cellularly and later on extra-cellularly.

30

PROCEDURE

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps.

35

- Step 5 EVAC containing cell populations are made using 10 different normalised and enriched cDNA libraries in each. EVACs are transformed into the cell population evolved in example 7.
- 5 1. Grow the carotenoid producing cell population to mid log, 2×10^6 to 2×10^7 cells/ml in liquid medium, at 30°C and with aeration, under selective conditions for the EVACs.
2. Spin to pellet cells at 400 x g for 5 minutes; discard supernatant.
3. Resuspend cells in a total of 9 ml TE, pH 7.5. Spin to pellet cells and discard supernatant.
- 10 4. Gently resuspend cells in 5 ml 0.1 M Lithium/Cesium Acetate solution, pH 7.5.
5. Incubate at 30°C for 1 hour with gentle shaking.
6. Spin at 400 x g for 5 minutes to pellet cells and discard supernatant.
7. Gently resuspend in 1 ml TE, pH 7.5. Cells are now ready for transformation.
8. In a 1.5 ml tube combine:
- 15 • 100 μ l yeast cells
- 5 μ l carrier DNA (10 mg/ml)
- 5 μ l Histamine Solution
- 5/100 of an EVAC preparation in a 10 μ l volume (max). (One EVAC preparation is made of 100 μ g of entry vector library plasmid mixture)
- 20 9. Gently mix and incubate at room temperature for 30 minutes.
10. In a separate tube, combine 0.8 ml 50% (w/v) PEG 4000 and 0.1 ml TE and 0.1 ml of 1 M LiAc for each transformation reaction. Add 1 ml of this PEG/TE/LiAc mix to each transformation reaction. Mix cells into solution with gentle pipetting.
11. Incubate at 30°C for 1 hour.
- 25 12. Heat shock at 42°C for 15 minutes; cool to 30°C.
13. Pellet cells in a microcentrifuge at high speed for 5 seconds and remove supernatant.
14. Resuspend in 200 μ l of rich media and plate in appropriate selective media
15. Incubate at 30°C for 48-120 hours until transformed colonies appear.
- 30
- Step 7 The screening population is not divided
- Step 8 Retinoic Acid Receptor Activation:
- a. The screening population is amplified ten times.
- 35 b. The EVAC containing cell population is mated with a reporter strain containing a reporter construct in an yeast vector and a yeast expression plasmid containing the cDNA for the human retinoic acid receptor (RAR β) and cultured under selection for the haploid cells, the reporter system and the EVACs. The reporter gene used is β -

galactosidase. The reporter strain is constructed essentially as described in Salerno et al. 1996, Nucleic Acids Res. 24(4), 566-72.

- c. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 μ M Cu_2SO_4 . The cells are grown under induction conditions for 18 hours. Growth and β -galactosidase activity are assayed in 96 well microtiter plates essentially as described in Coldham et al., 1997, Environ. Health Perspect., 105(7), 734-42.

- d. Cells with the 10% highest β -galactosidase activity are selected.

Step 9 There is no step 9.

Remixing of genetic diversity selected in step 8 is done by physical re-isolation and re-transformation of EVACs.

Step 10 The population selected in step 8 is grown in 5 ml of YPD to an $\text{OD}_{600} > 1.0$

Step 11 Two 100 μ l plugs of total DNA are produced as described in BioRad's "CHEF genomic DNA plug kits" manual, Procure n.2

Step 12 EVACs are purified and isolated:

- a. Plugs are cut and loaded into 3 slots of a pulsed field gel
- b. Run PFGE
 - i. For EVACs < 1000 kb : Chef III, 1% Agarose, 1/2 strength TBE, 6V/cm, 14°C, 120° angle, 50 – 90 sec. Switch time, 22 h runtime.
 - ii. For EVACs > 1000 kb. Chef III, 1% Agarose, 1/2 strength TBE, 6V/cm, 14°C, 120° angle, 60-120 sec. Switch time, 24 h runtime
- c. stain one lane to identify position of EVACs
- d. cut corresponding part of the two non-stained lanes and digest the agarose by agarase treatment following standard procedures e.g. Pulsed Field Gel Electrophoresis. A practical approach.(Ed. A.P. Monaco) Oxford University Press 1995.
- e. Concentrate agarased preparation to 100 μ L by ultrafiltration.(e.g. Microcon YM-30, Millipore)
- f. add 400 TE to retentate and repeat concentration step. Repeat and concentrate to 25 μ L

123

Step 13 EVACs are transformed into yeast as before.

Step 16 Step 8 is essentially repeated but the cell population is co-cultured together with a reporter strain under selection for both strains. Thus compounds that activate RAR β now have to be reasonably hydrophilic in order to cross the cell membranes. The producer strain is also transformed with P450s as described in example 1. This procedure allows the simultaneous screen for activation of RAR β , compound permeability and P450 metabolism.

Step 19 Commencing with the tenth cycle, in step 16, cells that show a similar activation of RAR β as 0.1 μ M of retinoic acid are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing

PRIORITISED SPECIES AND TAXONOMIC GROUPS:

- Species that metabolise carotenoids to retinoids: mammals (specially liver and retina tissues), fishes (liver), insects and other animals.

Example 10: Evolution of Taxol like compounds

UTILITY.

Taxol is a highly effective anticancer drug used widely in the treatment of various carcinomas, melanomas and sarcomas. The unique mode of action of this drug, as well as its outstanding potency makes Taxol one of the most efficacious anticancer agents in current use. Taxol promotes assembly of microtubules and prevents depolymerization. This induces bundles of stable microtubules and blocks cell cycle mitosis.

SCREENING & SELECTION STRATEGY

- Stabilisation of microtubule assembly. The microtubule assembly is scored by FACS using gel encapsulation and measuring light scatter.
- Growth inhibition of murine fibroblast cells. The growth inhibition assay is done using gel microdroplets and flow cytometry.

PROCEDURE

Taxol's biosynthesis pathway is thought to involve between 12 and 20 enzymatic steps starting from geranylgeranyl diphosphate. The first committed step in the formation of taxol involves the cyclisation of geranylgeranyl diphosphate. After a few more enzymatic steps, an intermediate called Baccatin-III is synthesised. This intermediate is available from renewable natural sources and can thus be used as a precursor to feed a cell population in order to evolve a population of cells able to produce Taxol like compounds. Once this has been achieved, the genes identified in the process should be locked. The number of steps from a yeast metabolite to Baccatin-III can be reduced by incorporating in the Taxol producing population the first genes of the pathway which are known: crtE (phytoene synthase) which can modify a yeast metabolite, IPP, to produce geranylgeranyl diphosphate, taxadiene synthase and taxadiene 5 α -hydroxylase. After a second module of evolution where no precursor feeding is used, a population of cells able to produce Taxol like compounds will have been established.

For each modular evolution the procedure as that described in Example 9 is performed, except that the following changes are made to the following numbered steps.

- 20
- Step 7 The screening population is divided into 2 equal portions. One of the portions is screened for stabilisation of microtubule assembly (step 8) and the other growth inhibition of murin fibroblast cells (step 9)
- 25 Step 8 Stabilisation of microtubule assembly:
- a. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 μ M Cu₂SO₄ and the cells are grown under inducing conditions for 24 hours prior to screening.
- 30 b. The EVAC containing cells are co-encapsulated with 5 mg tubulin /ml.
- c. Gel capsules are suspended in polymerisation buffer and incubated at 37 C for 1 h. A fraction of the population is passed through the flow cytometer to determine the average light scatter.

- d. In parallel a control population of microcapsules are incubated in the same buffer lacking GTP. The population is passed through the flow cytometer to establish light scatter of microcapsules containing de-polymerised tubulin.
- 5 e. The suspension is cooled to 5 °C for 30 min. and microcapsules maintaining a light scatter closest to the light scatter on the capsules containing polymerised tubulin is recovered and processed through step 10.
- 10 f. The 10% of the cell population with the highest light scatter is selected.
- Step 9 Growth inhibition of murine fibroblast cells:
- 15 a. The screening population is grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄. a. An EVAC containing cell population is grown under induction conditions.
- 20 c. Murine fibroblast cells are co-encapsulated with the EVAC containing cells in gel microdroplets in fibroblast growth media.
- d. Incubation is conducted for 24 hours, after which the droplets are screened by flow cytometry and the level of cell proliferation of the murine fibroblasts in each droplet is measured.
- 25 e. Droplets with the lowest cell proliferation are selected such that 10% of host cell lines entering the screen are selected.
- Step 10 Each of the populations selected in steps 8) and 9) is amplified. For each of the selected populations, steps 11-13 are repeated separately.
- 30 Step 16 The entire population is now screened simultaneously for stabilisation of microtubule assembly and for growth inhibition of murine fibroblast cells using a double gel encapsulation system.

Step 19 Cells that have an activity similar to that produced by a 10 nM concentration of Taxol are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing.

5

PRIORITISED SPECIES AND TAXONOMIC GROUPS

Sourced species are divided into:

- Species that produce Taxol and other Taxol like compounds,
- Organisms phylogenetically related to the Taxol producers
- 10 • Organisms known to have relevant pharmacological activities, i.e., anticancer
- Specific genes coding for enzymes known to be involved in the Taxol biosynthesis

15 Species that produce Taxol:

Plants: *Taxus brevifolia*, *Taxus cuspidata*, *Taxus yunnanensis*, *Taxus canadensis*, *Taxus baccata*, *Taxus wallichiana*, *Taxus mairei*, *Taxus chinensis*, *Taxus media*;
Fungii: *Taxomyces andreanae*, *Taxomyces wallichiana*, *Taxomyces baccata*, *Taxomyces canadensis*

20

Organisms phylogenetically related to the Taxol producers:

Same family: *Taxus globosa*, *Taxus biteminata*, *Taxus caespitosa*, *Taxus recurvata*, *Taxus umbraculifera*, *Taxus concorta*, *Taxus sumatrana*, *Torreya grandis*, *Torreya nucifera*; Cupressaceae Family : *Callitris arborea*, *Chamaecyparis lawsoniana*,
 25 *Cupressus arizonica*, *Juniperus chinensis*, *Juniperus recurvus*, *Tetraclinis articulata*, *Thuja occidentalis*, *Widdringtonia cupressoides*; Podocarpaceae Family : *Podocarpus ferrugineus*; Araucariaceae Family: *Agathis alba*, *Araucaria imbricata*, *Agathis australis*, Pinaceae Family: *Abies balsamea*, *Abies webbiana*, *Cedrus deodora*, *Larix europaea*, *Picea rubens*, *Pinus australis*, *Pinus pinaster*, *Pinus wallichiana*, *Pseudotsuga taxifolia*, *Tsuga canadensis*, Cephalotaxaceae family: *C. fortunei*, *C. Hauringtonii*, Sciadopityaceae family: *Sciadopitys verticillata*

30

Organisms reported to have antineoplastic activity:

PLANTS: *Chelidonium majus* (Celandine-plant), *Rheum officinale* (Chinese Rhubarb, Root), *Rheum rhabarbarum* (Rhubarb, Root), *Allium cepa* (Onion, bulb), *Aloe vera*

35

- (Aloe, plant), *Arachis hypogaea* (Groundnut, Seed), *Brassica oleracea* var. *capitata* (Cabbage, Leaf), *Cassia tora* (Sickle Senna, Seed), *Coptis chinensis* (Chinese Goldthread, Rhizome), *Coptis japonica* (Huang-Lia, Rhizome), *Coptis spp* (Generic Goldthread, Rhizome), *Corydalis spp* (Fumewort, Plant), *Eschscholzia californica* (California Poppy, Shoot), *Glaucium flavum* (Horned Poppy, Root), *Papaver somniferum* (Opium Poppy, Plant), *Polygonum multiflorum* (Chinese Cornbind, Root), *Rheum palmatum* (Chinese Rhubarb, Root), *Rumex hymenosepalus* (Canaigre, Root), *Sanguinaria canadensis* (Bloodroot, Root), *Senna alata* (Ringworm Bush, Plant), *Adonis vernalis* (Spring Adonis, Plant),
- 10 ANIMALS, Sponges: *Corticium sp*, *Zyzzya cf. fuliginosa*, *Chondropsis sp*, *Diacarnus erythraenus*; jellyfish: *Carybdea rastonii*, *Chrysaora quinquecirrha*; anemones: *Actinia equina*, *Anemonia viridis*, Insects: *Papilio polyxenes*, *Drosophila melanogaster*, *Rhodnius prolixus*, *Apis mellifera*, *Lacanobia oleracea*; Spiders: *Tarantula keratouveitis*, *Loxosceles deserta*, *Loxosceles reclusa*; Crabs: *Clibanarius longitarsus*, *Tachypleus tridentatus*, *Uca pugilat*, Worms: *Schistosoma mansoni*, Snails: *Lippia sidoides*, *Lymnaea stagnalis*, *Stylocheilus longicauda*, *Biomphalaria glabrata*; Snakes: *Bothrops jararaca*, *Crotalus durissus*, *Vipera aspis*, *Sistrurus Malarius Barbouri*; Sea urchin: *Toxopneustes pileolus*; Starfish: *Acalycigorgia inermis*, *Asterina pectinifera*, *Fromia monilis*,

20

Evolution of cells towards specific drug targets

Example 11: Evolution of HIV protease inhibitors

25 UTILITY.

Acquired immunodeficiency syndrome (AIDS) is a fatal pathogenic disease caused by the HIV virus. AIDS is prevalent in almost every country on the globe, and it is estimated that 36 million people are infected worldwide. HIV Protease is an enzyme expressed by the HIV Virus. Molecules that inhibit HIV Protease have utility in the treatment of HIV infections. Desirable attributes of such molecules include activity against HIV, specificity for HIV protease, ability to cross cell membranes in order to reach the virus and others.

30

SCREENING & SELECTION STRATEGY

Assays that measure the activity of HIV Protease can be constructed by labelling the protein substrate of the protease with a fluorescent dye such that in the undigested substrate the fluorescence is quenched but in the enzymatically digested substrate the fluorescence is unquenched. Procedures for constructing such screens are given in "Activity and dimerization of human immunodeficiency virus protease as a function of solvent composition and enzyme concentration." Jordan SP, Zugay J, Darke PL, Kuo LC. J Biol Chem 267, 20028-20032 (1992).

PROCEDURE.

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

- | | |
|---------|--|
| Step 7 | The screening population is not divided. |
| Step 8 | The EVAC containing cell population is grown for 12 hours under conditions that induce expression. A reporter assay constructed as above is incorporated proximal to the host cell in a microdroplet. The microdroplet is incubated in screening medium. At 2 hour intervals 10% of the microdroplets are run through a flow cytometer and screened for level of fluorescence. In each 2 hour batch those droplets with the lowest level of fluorescence are selected such that statistically 10% of host cell lines are represented in the selected cells. Selected cells are immediately placed into media that halts induction of the heterologous genes. The selected cells from each batch are pooled |
| Step 9 | There is no step 9 |
| Step 10 | The population selected in step 8 is amplified |
| Step 16 | Cells are now screened simultaneously for P450 metabolism and HIV protease inhibition. The selection criteria are set such that 5% of the cell lines entering the screen are selected |

Step 19 Cells that inhibit HIV protease to the same extent as Indinavir does at a 25nM concentration are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing

5

PRIORITISED SPECIES AND TAXONOMIC GROUPS

- Random group of taxonomically diverse eukaryotic species

Example 12: Evolution of DNA Topoisomerase II Poisons

10

UTILITY.

Topoisomerase II is an essential enzyme in cell division – it regulates the topology of DNA and in particular performs a process whereby it cuts open double stranded DNA, passes another strand through the break, and then reseals the break.

15

Compounds (such as doxorubicin and etoposide) that cause the topoisomerase II enzyme to generate but not seal these DNA double strand breaks have proven utility as anti-cancer agents. New compounds with such activity but different pharmacological properties have utility as compounds for the treatment of cancer, and indeed other proliferative diseases.

20

SCREENING & SELECTION STRATEGY

Topoisomerase II poisons (such as doxorubicin and etoposide) are preferentially toxic to cells that have high levels of topoisomerase II – their toxic effect is achieved by causing the topoisomerase enzyme to generate double strand breaks in DNA.

25

Their effects are antagonised by compounds (such as chloroquine and dexrazoxane) that act on the enzyme without causing the double strand breaks. These properties can be used to construct a process for selecting and evolving cells that produce compounds that act as topoisomerase poisons

30

Yeast host cells are described in the scientific literature that conditionally express functional human topoisomerase II, Wasserman R. et al, Cancer Research, 1993, 53, 3591.

35

PROCEDURE

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

- 5 Step 5. EVAC containing cell populations are made using 10 different normalised and enriched cDNA libraries.
- Step 7 The screening population is not divided.
- 10 Step 8 Topoisomerase Inhibitory activity:
- a. The population is grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- 15 b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ and at 35°C. The cells are grown under induction conditions for 12 hours. Every 3 hours 25 % of the cell population is screened for DNA damage by flow cytometry. The 25% of cells in each titre showing least DNA damage are discarded and the remainder immediately placed in non-inducing media that contains dexrazoxane at 100 micromolar concentration
- 20 c. Those cells that survive and are selected from step 8b are resuspended and grown under induction conditions for a further 12 hours, but this time with dexrazoxane at 100 micromolar concentration throughout the 12 hour period At the end of the period the cells are screened for DNA damage by flow cytometry and cells representing
- 25 the 25% of cell lines showing least DNA damage are selected.
- Step 9 Inhibition of cancer cell growth:
- a. The population is grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- 30 b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ and at 35°C. The cells are plated and grown under induction conditions for 48hours. A cancer cell line is overlayed on the induced cell population. Yeast cells present in zones clear of cancer cells are selected.
- 35

- Step 10 The population selected in steps 8 and 9 are amplified
- 5 Step 16 The cell population is now screened simultaneously for DNA topoisomerase II inhibition and for growth inhibition of cancer cells using a double gel encapsulation system.
- 10 Step 19 Commencing with the tenth cycle cells that show DNA damage of an equivalent level to that caused by the addition of 5 micromolar etoposide and that show cancer cell growth inhibition are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing

PRIORITISED SPECIES AND TAXONOMIC GROUPS

- 15 • Plants that produce podophyllotoxins
- Species generally known to have anticancer activity

Example 13: Evolution of p53 Activators

20 UTILITY

p53 is a well known tumour suppressor gene that induces apoptosis in otherwise oncogenic cells. Dysfunctional p53 can mean that the apoptosis does not occur and the oncogenic cell proliferates. A large proportion of tumours have dysfunctional p53 protein.

- 25 p53 protein acts as a transcription factor. Many forms of dysfunctional p53 have lost the ability to act as a transcription factor. Tumour cells with such a dysfunctional form accumulate the p53 protein but transcription and hence apoptosis does not occur. In such tumour cells, compounds that restore the ability of such dysfunctional
- 30 p53 to initiate transcription, and hence apoptosis would have utility as anti-cancer agents. Rastinejad F., Science, 1999, 286, 2507-2510.

SCREENING & SELECTION STRATEGY

- 35 p53 is a transcription factor. A standard intracellular reporter system for p53 comprises a) a genetic construct whereby a gene encoding for GFP or a similar

reporter protein is placed under the control of a heterologous p53 inducible promoter, together with b) an inducible genetic construct encoding for a dysfunctional p53. Such a construct can be used to screen for compounds that activate the transcription of the GFP.

5

PROCEDURE

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

- 10 Step 5. EVAC containing cell populations are made using 10 different normalised and enriched cDNA libraries in each. The cell populations are then further transformed according to standard protocols with a p53 reporter system as described above
- 15 Step 7 The screening population is not divided
- Step 8 p53 activation screen:
- a. The population is grown in liquid culture under selective conditions for the artificial chromosomes and the p53 reporter system to an OD₆₀₀ of 0.6 – 1.0.
- 20 b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ and the cells are grown under induction conditions for 36 hours. Any cells producing GFP are discarded.
- 25 c. The dysfunctional p53 is induced and induction maintained for 5 days, alongside induction/de-repression of the EVAC genes. Cells are observed for production of GFP after 1 hour and then at 12 hour intervals throughout the five days. Those cells that produce GFP are selected.
- 30 Step 9 There is no step 9
- Step 10 The populations selected in step 8) is amplified

133

Step 16 Each cell is gel encapsulated and allowed to grow to form clonal sub populations. Clonal populations are double gel encapsulated with a tumour cell line and the gel droplets are screened for GFP production and induction of apoptosis. The selection criteria are set such that 5% of the cell lines entering the screen are selected.

Step 19 Cells that produce GFP within 1 hour of induction and induce apoptosis are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing.

PRIORITISED SPECIES AND TAXONOMIC GROUPS

- Organisms reported to have anticancer properties (see list in example 10)
- Random group of taxonomically diverse eukaryotic species

Example 14: Evolution of Fumarate Reductase inhibitors

UTILITY

Fumarate reductase reduces fumarate to succinate and is an essential step in anaerobic metabolism for many organisms including pathogens from such genera as Leishmania, Helicobacter, Staphylococcus and Streptococcus.

Compounds that inhibit the activity of fumarate reductase can prevent such parasites or pathogens from completing their life cycle and hence are of utility in controlling such diseases. Because fumarate reductase does not occur in humans, such compounds should not have significant toxicity to humans.

SCREENING & SELECTION STRATEGY

Fumarate reductase activity is measured by the rate at which it oxidises NADH upon the addition of fumarate. The progress of the enzymatic reaction is measured spectrophotometrically at 340nm. For detailed protocols see Chen et al., Antimicrob. Agents Chemother., 2002, 2023-2029.

PROCEDURE

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

- 5 Step 7 The screening population is not divided
- Step 8 Fumarate reductase screen:
- 10 a. The screening population is amplified ten times
- b. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 μ M Cu_2SO_4 and the cells are grown under inducing conditions for 24 hours prior to screening.
- 15 c. Fumarate reductase is co-encapsulated with EVAC containing cells in a gel microdroplet.
- d. Microdroplets containing fumarate reductase but not EVAC containing cells were incubated in a liquid media containing 100 micromolar NADH and 1mM fumarate and incubated at 30 C. Aliquotes were analysed by flow cytometry to determine the optimal incubation time.
- 20 e. The microdroplet is placed in a liquid media that contains 100 micromolar NADH and 1mM fumarate and incubated for the optimal period of time.
- 25 f. The gel microdroplets are then passed through a flow cytometer and absorption at 340nm measured. The activity of the enzyme is calculated from the level of absorption at 340nm. The cells with the lowest activity of enzyme are selected such that cells representing the 10% of cell lines entering the screen with the greatest inhibition of fumarate reductase are selected
- 30 Step 9 There is no step 9
- Step 10 The populations selected in step 8 is amplified.
- Step 16 Gel droplets are double encapsulated with *S. aureus* and gel droplets are screened simultaneously for fumarate reductase inhibition and

bacterial cell growth inhibition. The selection criteria are set such that 5% of the cell lines entering the screen are selected

- 5 Step 19 Cells that show inhibition of fumarate reductase and *S. aureus* growth inhibition of a same or greater extent than is achieved by adding licochalcone to the droplets at a concentration of 1 micromolar are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing.

10 **PRIORITISED SPECIES AND TAXONOMIC GROUPS**

- Plant roots
- Random group of taxonomically diverse eukaryotic species

Evolution of function independent of specific targets

15

Example 15: Evolution of cytoprotectants

UTILITY

- 20 One of the central problems of cancer chemotherapy is that the anti-cancer agents used kill normal cells as well as cancer cells. The side effects of killing the normal cells can be so severe as to be life-threatening, and frequently mean that treatment of the cancer has to be abandoned. Compounds that protect cells against such anti-cancer agents therefore have utility in reducing the side effects of cancer chemotherapy, hence improving both therapeutic outcome and patient life quality.
- 25 Existing examples of such compounds include dexrazoxane and chloroquine, both of which protect cells against the cytotoxic effects of cancer agents such as etoposide. However more such protectants are needed.

SCREENING & SELECTION STRATEGY

- 30 Host cells can be induced screened and selected for survival in the presence of cytotoxic anti-cancer agents such as doxorubicin, taxol, vincristine and cisplatin. Over a series of selection rounds the concentration of cytotoxic agent that a cell must survive to be selected can be increased

35 **PROCEDURE**

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

- 5 Step 7 The screening population is divided into two equal portions. One of the portions is screened against etoposide (step 8) and the other screened against vincristine (step 9)
- 10 Step 8 Etoposide screen:
- 15 a. The screening population is amplified ten times and divided in 10 portions.
- b. The sub populations are grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- c. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ and the cells are grown under induction conditions for 36 hours prior to screening.
- 20 d. Each sub population is diluted so as to have on average each cell line represented 3 times.
- e. Each sub population is exposed to 1 out of a range of 10 concentrations of etoposide. Survival rates are determined after 2 hours. The surviving cell population from the highest concentration of etoposide where cells statistically representing 10% of the cell lines survived is selected.
- 25 Step 9 Vincristine screen:
- a. The screening population is amplified ten times and divided in 10 portions.
- b. The sub populations are grown in liquid culture under selective conditions for the artificial chromosomes to an OD₆₀₀ of 0.6 – 1.0.
- 30 c. The heterologous genes are induced/de-repressed by re-suspending the cells in a medium lacking methionine and with 200 µM Cu₂SO₄ and the cells are grown under induction conditions for 36 hours prior to screening.
- d. Each sub population is exposed to 1 out of a range of 10 concentrations of vincristine. Survival rates are determined after 2 hours. The
- 35

surviving cell population from the highest concentration of vincristine where cells statistically representing 10% of the cell lines survived is selected.

- 5 Step 10 Each of the populations selected in steps 8) and 9) is amplified and equal amounts of each amplified population are pooled
- 10 Step 16 The entire population is now screened for both etoposide and vincristine resistance. The selection criteria are set such that 5% of the cell lines entering the screen are selected
- 15 Step 19 Cells that, compared to the original population, show the ability to resist a 10-fold higher concentration of etoposide, or a 10-fold higher concentration of vincristine, or a combined 5-fold higher dose of both together, are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing.

PRIORITISED SPECIES AND TAXONOMIC GROUPS

- 20
 - Plant species of the genera Vinca
 - Organisms known to produce Taxol (see list in example 10)

Example 16: Evolution of antibacterials

25 UTILITY

The widespread emergence of resistance has significantly limited the efficacy of classical antibiotic therapy for bacterial disease. Fuelled largely by the excessive and often unnecessary use of antibiotics in humans and animals, antibiotic resistance has resulted in increased patient morbidity, mortality and overall cost of health care.

30

There is a strong medical need for new therapeutics to treat emerging antibiotic-resistant infections. A premium is placed upon inhibitors that function by a novel or at least different mechanism than currently approved antibiotics, as these would be expected to circumvent current bacterial resistance mechanisms.

35

SCREENING & SELECTION STRATEGY

Screening can be done using gel microdroplets and flow cytometry or an overlay system. Use of a multiple drug-resistant strain in the primary screen will *a priori* select for hits that have activity against a multi-drug resistant strain.

The approach set out in this example can be applied to a range of micro-organisms other than the one described here. Mammalian cells can be used in one or more selection rounds and used to select for host cells that are not producing compounds with mammalian cell toxicity.

PROCEDURE

The same procedure as that described in Example 7 is performed, except that the following changes are made to the following numbered steps

15

Step 7 The screening population is not divided.

Step 8 Antibacterial screen:

20

a. An EVAC containing cell population is grown under induction conditions.

b. *Staphylococcus aureus* is co-encapsulated with the EVAC containing cells in gel microdroplets.

25

c. Incubation is conducted for 24 hours, after which the droplets are screened by flow cytometry and the level of cell proliferation by the bacteria in each droplet is measured.

d. Droplets with the lowest cell proliferation are selected such that 10% of host cell lines entering the screen are selected.

30

Step 9 The cell population is transformed with CYP 3A4, CYP 2C9 and CYP 2D6.

Step 10 The population selected in step 8 is amplified.

Step 16 The population is now screened for inhibition of bacterial growth and inhibition of CYP 3A4, CYP 2C9 and CYP 2D6. The selection criteria are set such that 5% of the cell lines entering the screen are selected

5 Step 19 Cells that have shown an antibacterial activity equal to that achieved with vancomycin at a concentration of 1 µg/ml and that do not inhibit the P450s are taken out of the evolution process. The genes responsible for these activities are characterised by subcloning and DNA sequencing

10

5 **Example 18: Concatemer size limitation experiments (use of stoppers)**

Materials used:

pYAC4 (Sigma. Burke et al. 1987, science, vol 236, p 806) was digested w. EcoR1 and BamH1 and dephosphorylated

10 pSE420 (invitrogen) was linearised using EcoR1 and used as the model fragment for concatenation.

T4 DNA ligase (Amersham-pharmacia biotech) was used for ligation according to manufacturers instructions.

15 Method: Fragments and arms were mixed in the ratios(concentrations are arbitrary units) indicated on figures. Ligation was allowed to proceed for 1 h at 16C. Reaction was stopped by the addition of 1 µL 500 mM EDTA. Products were analysed by standard agarose GE (1 % agarose, ½ strength TBE) or by PFGE(CHEF III, 1% LMP agarose, ½ strength TBE, angle 120, temperature 12 C, voltage 5.6V/cm, 20 switch time ramping 5 – 25 s, run time 30 h)

The results are shown in Figure 17a and 17b.

25 **Example 19: Expression of different patterns “phenotypes” obtained using the same yeast clones under different expression conditions**

Colonies were picked with a sterile toothpick and streaked sequentially onto plates corresponding to the four repressed and/or induced conditions (-Ura/-Trp, -Ura/-Trp/-Met, -Ura/-Trp/+200 µM Cu₂SO₄, -Ura/-Trp/-Met/+200 µM Cu₂SO₄). The result 30 is shown in Figure 24.

Claims

1. A method for screening a cell producing at least one compound, said screening being for two or more functionalities of said compound, said method comprising the steps of
 - a) providing a composition of cells, said composition of cells comprising cells each with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition contain different heterologous expressible nucleotide sequences, said cells being denoted producer cells,
 - b) performing one screening of said population of cells for at least 2 parameters related to the functionalities, and determining a selection criterion for each parameter,
 - c) selecting cells meeting at least one predetermined selection criterion.
2. The method according to claim 1, wherein the compound is contained within said cell.
3. The method according to claim 1 or 2, wherein the compound is excreted from said cell.
4. The method according to any of the preceding claims, wherein step c) comprises selecting cells meeting a predetermined value of more than one parameter, preferably of each parameter.
5. The method according to any of the preceding claims, wherein at least one parameter is a parameter related to activity against a pharmacological target,
6. The method according to any of the preceding claims, wherein at least one parameter is a parameter related to activity against a pharmacological target, and at least one further parameter is an ADME parameter.

7. The method according to any of the preceding claims, wherein at least one parameter is a parameter related to a desired pharmacological property and another parameter is related to an undesired pharmacological property.
- 5 8. The method according to any of the preceding claims, wherein a parameter related to activity against a pharmacological target is interaction or non-interaction with a ligand pharmacological target.
- 10 9. The method according to any of the preceding claims, wherein a parameter related to activity against a pharmacological target is interaction or absence of interaction with an enzyme pharmacological target.
- 15 10. The method according to any of the preceding claims, wherein a parameter related to activity against a pharmacological target is interaction or non-interaction with a receptor pharmacological target.
- 20 11. The method according to any of the preceding claims, wherein a parameter related to activity against a pharmacological target is inhibition or enhancement of expression of a gene or a set of genes encoding a pharmacological target.
- 25 12. The method according to claim 11, wherein the inhibition or enhancement of expression is caused by the ability of a compound to bind to the promoter sequence of the target gene, or the ability to bind to or not bind to transcription factors.
- 30 13. The method according to any of the preceding claims, wherein a parameter related to activity against a pharmacological target is inhibition of growth of a reporter cell.
- 35 14. The method according to any of the preceding claims, wherein a parameter related to activity against a pharmacological target is stimulation of growth of a reporter cell.
15. The method of claim 13 or 14, wherein the cell is selected from a group consisting of bacteria, fungi, protozoa, helminth, algae, plants, invertebrates,

vertebrates, mammalian cells, pathogenic microorganisms, agricultural pests, cells infected by an intracellular pathogen, virus-infected cells, tumor cells.

- 5 16. The method of claim 13 or 14, wherein the reporter cell is a whole live organism, e.g., bacteria, fungi, protozoa, algae, plants, invertebrates, insects, tardigrada, parasites, agricultural pests.
- 10 17. The method according to any of the preceding claims, wherein the cell has been transformed to produce at least one drug metabolising enzyme.
18. The method of claim 17, wherein the drug metabolising enzyme is selected from Cytochrome P450s, Flavin monooxygenases, UDP glycosyltransferases, Glutathione transferases, Sulfotransferases, N-acetyltransferases.
- 15 19. The method according to claim 18, wherein the drug metabolising enzyme is a Cytochrome P450, such as at least one P450 being selected from the group consisting of CYP1A2, CYP2B6, CYP2C19, CYP2C9, CYP2D6, CYP2E1, CYP3A4, CYP3A5, CYP3A7, CYP2C8, CYP2C18 and their allelic variants.
- 20 20. A method according to claim 18, wherein the drug metabolising enzyme is a UDP glycosyltransferases, UGTs, such as at least one UGT selected from the group consisting of UGT1A1, UGT1A3, UGT1A4, UGT1A6, UGT1A9, UGT2B4, UGT2B7, UGT2B10, UGT2B11, UGT2B15.
- 25 21. A method according to claim 18, wherein the drug metabolising enzyme is a Glutathione transferases, GST, such as GST A1-1, GST M1-1, GST P1-1.
22. A method according to claim 18, wherein the drug metabolising enzyme is a Sultotransferases (SULTs) such as SULT1A1, SULT1A2, SULT1A3, SULT1E, 30 SULT2A1.
23. The method according to any of the preceding claims 17 to 22, wherein the drug metabolising enzyme is placed externally to the cells with the heterologous expressible nucleotide sequences.
- 35

24. The method according to claim 17 to 22, wherein the drug metabolising enzyme is placed outside the cells with the heterologous expressible nucleotide sequences, or in reporter cell.
- 5 25. The method according to any of the claims 17 to 23, wherein at least one drug metabolising enzyme is placed outside the cells with the heterologous expressible nucleotide sequences, and at least one is placed inside said cells.
- 10 26. The method according to any of the claims 17 to 25, wherein at least two different drug metabolising enzyme are used, such as at least 3, for example at least 4, such as at least 5, for example at least 7, such as at least 10.
- 15 27. The method according to any of the preceding claims, wherein one functionality is the ability of the compound to be taken up by a mammalian cell, including a human cell.
- 20 28. The method according to claim 27, wherein one functionality is screened by culturing the cells in connection with immortalised mammalian cells and detecting the effect of the compound or a metabolite of the compound in a receiver compartment.
- 25 29. The method according to claim 28, wherein the cultured immortalised cells are grown in a confluent monolayer and compounds with desirable permeabilities are selected.
- 30 30. The method according to claim 28 or 29, wherein the cultured immortalised cells are liver, epidermal, epithelial, nasal, or lung cells.
31. The method according to claim 28, wherein the cultured immortalised cells are selected from the group comprising human colon carcinoma cell line, dog kidney cell line, the Madin-Derby Canine kidney cell line (MDCK), everted intestinal rings, brush-border membrane vesicles (BBMV).
- 35 32. The method according to any of the claims 28-31, wherein the cultured immortalised cells express one or more of: the apically located efflux pumps, P-

glycoproteins, monocarboxylic acid transporters, dipeptide transporters, transporters for large neutral amino acids, ABC-transporters (e.g. Pgp/MDR1, MRP1, MRP2, MDR3, MRP3, MRP5, MRP6, MXR, BCRP, ABCG2).

- 5 33. The method according to any of the preceding claims, wherein the activity of at least one drug resistance pump of the host cell is controlled by an externally controllable promoter.
- 10 34. The method according to any of the preceding claims, wherein one functionality is toxicity.
35. The method according to claim 34, wherein toxicity is screened by using a cell proliferation assay
- 15 36. The method of claim 35, comprising the use of freshly isolated human hepatocytes, human liver cell lines such as ACTIVTox and/or Hep G2.
37. The method according to any of the preceding claims, wherein one functionality is mutagenicity.
- 20 38. The method according to claim 37, wherein mutagenicity is measured by the rate of reverse-mutation in an organism
39. The method of claim 38, wherein said organism is an animal cell, or more preferably a microorganism.
- 25 40. The method according to any of the preceding claims, wherein one functionality is teratogenicity.
41. The method according to any of the preceding claims, wherein two or more functionalities are related to the same target, such as the same enzyme.
- 30 42. The method according to any of the preceding claims, comprising performing at least one screening for at least 3 parameters related to the two or more functionalities.
- 35

43. The method according to any of the preceding claims, comprising performing at least one screening for at least 4 parameters related to the two or more functionalities.
- 5
44. The method according to any of the preceding claims, comprising performing at least one screening for at least 5 parameters related to the two or more functionalities, such as at least 6 parameters, for example at least 7 parameters, such as at least 8 parameters, for example at least 9 parameters, such as at least 10 parameters, for example at least 15 parameters, such as at least 20 parameters, for example at least 25 parameters, such as at least 50 parameters.
- 10
45. The method according to any of the preceding claims, wherein the strength of the selection criteria/criterion is increased for at least some of the repeats.
- 15
46. The method according to any of the preceding claims, wherein the type of selection criteria/criterion is changed for at least some of the repeats.
47. The method according to any of the preceding claims, wherein the strength of the selection criterion/criteria increases with the repeats and/or the type of selection criteria is changed for at least some of the repeats.
- 20
48. The method according to any of the preceding claims, wherein one parameter related to the two or more functionalities in an early round of screening is a generic parameter, and one parameter related to the functionality in a later round is a more specific parameter.
- 25
49. The method according to any of the preceding claims, wherein the number of parameters screened for simultaneously increases with the number of screening rounds.
- 30
50. The method according to any of the preceding claims, wherein at least one screening is a medium based screen, such as using unusual substrates, growing cells on toxin comprising medium, growing cells on inhibitor comprising medium.
- 35

51. The method according to any of the preceding claims, wherein at least one selection criterion is selection on the basis of survival, superior growth, deviating morphology, stickiness, spectral properties, (modulation of) enzyme activity.

5 52. The method according to any of the preceding claims wherein at least one selection criterion is selected from at least one physical criterion, such as temperature, osmolarity, light, and electricity, leading to cells being selected on the basis of survival, superior growth, deviating morphology, stickiness, spectral properties, (modulation of) enzyme activity.

10

53. The method according to any of the preceding claims, wherein at least one selection criterion is the capability of survival of cells when grown in media having increasing concentrations of a substance compared to what the unmodified cell can survive.

15

54. The method according to any of the preceding claims, wherein the two or more functionalities are related to production of non-native metabolites, preferably secondary metabolites.

20 55. The method according to any of the preceding claims, comprising the use of a fluorescent analyser.

56. The method according to any of the preceding claims, wherein the selection of positive cells meeting the at least one selection criterion is performed by means of fluorescence activated cell sorters (FACS).

25

57. The method according to claim 56, wherein the sorting is based on a signal from an intracellular reporter system, said reporter system being native or heterologous.

30

58. The method of claim 56, wherein at least two selection criteria are selected on by means of FACS, such as at least 3 criteria, for example at least 4 criteria, such as at least 5 criteria, for example at least 7 criteria, such as at least 10 criteria.

35

59. The method according to claim 56, wherein at least 10,000 cells are sorted by the cells sorters per second, more preferably at least 50,000 per second, more preferably at least 100,000 per second, more preferably at least 200,000, more preferably at least 500,000, more preferably at least 750,000, more preferably at least 1,000,000 per second.
60. A method according to any of the preceding claims, wherein the selection of positive cells meeting the at least one selection criterion is performed by means of survival in the presence of other organisms.
61. A method according to any of the preceding claims, wherein the selection of positive cells meeting the at least one selection criterion is performed by means of having a growth advantage in media where growth requires the expression of reporter genes that when giving a desired response produces a compound vital for cell survival, e.g. antibiotic resistance marker, cell cycle control proteins, auxotrophic markers.
62. The method according to any of the preceding claims to 50 to 61, wherein selection comprises use of any of the selection methods in any order.
63. The method according to any of the preceding claims to 50 to 61, wherein selection comprises any combination of the selection methods.
64. The method according to any of the preceding claims, wherein the cells are enclosed in a screening unit comprising reporter systems.
65. The method according to claim 64, wherein the cells are enclosed into liposomes, beads, ghost red blood cells or ghost macrophages.
66. The method according to claim 64, wherein the cells are enclosed in gel droplets comprising agarose, polysaccharide, carbohydrate, alginate, carrageenan, chitosan, cellulose, pectin, dextran, or polyacrylamide.
67. The method according to claim 64, wherein the cells are enclosed in a layer essentially non-penetrable by the compounds being screened.

68. The method according to claim 64, wherein the non-penetrable material is a lipid material.
- 5 69. The method according to claim 64, wherein cells are encapsulated into gel droplets comprising reporter system(s) prior to sorting by FACS.
70. The method according to claim 64, wherein the cells and the reporter system(s) are encapsulated into one layer of gel droplets.
- 10 71. The method according to claim 64, wherein one layer comprises the producer cells and one or more reporter system(s), and a second layer comprises one or more different reporter system(s), and optionally a third or fourth or further layer comprises one or more reporter system(s).
- 15 72. The method according to claim 64, wherein the producer cell is encapsulated in one layer of the gel droplet and at least one reporter system is encapsulated in another layer of the same gel droplet.
- 20 73. The method according to claim 64, wherein the producer cell is encapsulated in one layer of the gel droplet and a first reporter system is encapsulated in another layer of the same gel droplet and at least a second reporter system is encapsulated into yet another layer of the same gel droplet.
- 25 74. The method according to claim 64, wherein the producer cell is encapsulated in one gel droplet and one or more reporter systems are encapsulated in one or more separate gel droplets and all these gel droplets are encapsulated together in a gel droplet to form a screening unit.
- 30 75. The method according to any of the preceding claims, wherein the selection of positive cells meeting the at least one selection criterion is performed by means of an overlay assay, said overlay assay comprising reporter system(s), and manual or automatic picking of positive cells.

- 5 76. The method according to any of the preceding claims, wherein the selection of positive cells meeting the at least one selection criterion is performed by means of placing a single clonal producer cell line in one well of a microtiterplate, said well comprising reporter system(s), and manual or automatic picking of positive cells.
- 10 77. The method according to any of the preceding claims, wherein said reporter system is a cell based reporter system, being native to the reporter cell or being heterologous to the reporter cell.
78. The method according to any of the preceding claims, wherein said reporter system is a cell free reporter system.
- 15 79. The method according to any of the preceding claims, wherein the selection of positive cells meeting the at least one selection criterion is performed by means of plating cells on a medium, and manual or automatic picking of positive cells.
80. The method according to any of the preceding claims, wherein a composition of cells comprises at least 20 genetically different cells.
- 20 81. The method according to any of the preceding claims, wherein a composition of cells comprises at least 10^3 genetically different cells, more preferably at least 10^4 , more preferably at least 10^5 , more preferably at least 10^6 .
- 25 82. The method according to any of the preceding claims, wherein a composition of cells comprises at least 10^7 genetically different cells, such as at least 10^8 genetically different cells, for example at least 10^9 genetically different cells, for example at least 10^{10} , such as at least 10^{11} , for example at least 10^{12} , such as at least 10^{13} , for example at least 10^{14} , such as at least 10^{16} , for example at least 10^{18} , such as at least 10^{20} .
- 30 83. The method according to any of the preceding claims, wherein a composition of cells comprises a collection of cells from one species.

84. The method according to claim 1, wherein the producer cells comprise at least 10 different heterologous expressible nucleotide sequences, such as at least 15, for example at least 20, such as at least 25, for example at least 30, such as from 30 to 60 or more than 60, such as at least 75, for example at least 100, such as at least 200, for example at least 500, such as at least 750, for example at least 1000, such as at least 1500, for example at least 2000.
85. The method according to claim 84, wherein the different expressible nucleotide sequences come from the same or from different expression states.
86. The method according to any of the preceding claims, wherein substantially all heterologous expressible nucleotide sequences are located on one or more artificial chromosomes.
87. The method according to any of the preceding claims, wherein the composition of cells comprises at least one cell, said at least one cell comprising:
- a) at least two expression cassettes of the following formula:
[rs₂-SP-PR-X-TR-SP-rs₁]
wherein
rs₁ and rs₂ together denotes a restriction site,
SP individually denotes a spacer,
PR denotes a promoter, capable of functioning in said at least one cell,
X denotes an expressible nucleotide sequence,
TR denotes a terminator, and/or
 - b) at least two expressible nucleotide sequences, said sequences being heterologous to the cell.
88. The method according to any of the preceding claims, wherein the at least two expressible nucleotide sequences are individually selected from a gene or a full-length cDNA sequence.
89. The method according to any of the preceding claims, wherein at least one cell of the composition comprises at least one concatemer of individual

oligonucleotide cassettes, each concatemer comprising an oligonucleotide of the following formula in 5'→3' direction

[rs₂-SP-PR-X-TR-SP-rs₁]_n

5

wherein

rs₁ and rs₂ together denote a restriction site,

SP individually denotes a spacer of at least two nucleotide bases,

10

PR denotes a promoter, capable of functioning in said at least one cell,

X denotes an expressible nucleotide sequence,

TR denotes a terminator, and

wherein $n \geq 2$, and

15

wherein at least two expressible nucleotide sequences are from different expression states.

90. The method according to claim 85 or 89, wherein the at least two different expression states represent at least two different tissues, such as at least two organs, such as at least two species, such as at least two genera.

20

91. The method according to claim 90, wherein the two different species are from at least two different phylae, such as from at least two different classes, such as from at least two different divisions, more preferably from at least two different sub-kingdoms, such as from at least two different kingdoms.

25

92. The method according to claim 90, wherein one species is a eukaryote and another species is a prokaryote.

93. The method according to claim 87 or 89, wherein substantially all rs₁-rs₂ sequences are recognised by the same restriction enzyme, more preferably wherein substantially all rs₁-rs₂ sequences are substantially identical.

30

94. The method according to claim 87 or 89, wherein n is at least 10, such as at least 15, for example at least 20, such as at least 25, for example at least 30, such as from 30 to 60 or more than 60, such as at least 75, for example at least

35

100, such as at least 200, for example at least 500, such as at least 750, for example at least 1000, such as at least 1500, for example at least 2000.

- 5 95. The method according to any of the preceding claims, wherein the producer cell comprises a prokaryotic cell selected from the group comprising bacteria such as *Escherichia coli*, *Bacillus subtilis*, *Streptomyces lividans*, *Streptomyces coelicolor* *Pseudomonas aeruginosa*, *Myxococcus xanthus*.
- 10 96. The method according to any of the preceding claims, wherein the producer cell comprises a eukaryotic cell selected from the group comprising: yeasts; filamentous ascomycetes such as *Neurospora crassa* and *Aspergillus nidulans*; plant cells such as those derived from *Nicotiana* and *Arabidopsis*; mammalian host cells such as those derived from humans, monkeys and rodents, such as chinese hamster ovary (CHO) cells, NIH/3T3, COS, 293, VERO, HeLa.
- 15 97. The method according to claim 96, being a yeast cell selected from the group comprising baker's yeast, *Kluyveromyces marxianus*, *K. lactis*, *Candida utilis*, *Phaffia rhodozyma*, *Saccharomyces boulardii*, *Pichia pastoris*, *Hansenula polymorpha*, *Yarrowia lipolytica*, *Candida paraffinica*, *Schwanniomyces castellii*,
20 *Pichia stipitis*, *Candida shehatae*, *Rhodotorula glutinis*, *Lipomyces lipofer*, *Cryptococcus curvatus*, *Candida* spp. (e.g. *C. palmioleophila*), *Yarrowia lipolytica*, *Candida guilliermondii*, *Candida*, *Rhodotorula* spp., *Saccharomycopsis* spp., *Aureobasidium pullulans*, *Candida brumptii*, *Candida hydrocarbofumarica*,
25 *Torulopsis*, *Candida tropicalis*, *Saccharomyces cerevisiae*, *Rhodotorula rubra*, *Candida flaveri*, *Eremothecium ashbyii*, *Pichia* spp., *Kluyveromyces*, *Hansenula*, *Kloeckera*, *Pichia*, *Pachysolen* spp., *Schizosaccharomyces pombe* (fission yeast), or *Torulopsis bombicola*.
- 30 98. The method according to any of the preceding claims, wherein the producer cell has at least one mutation in a central biosynthetic pathway.
- 35 99. The method according to claim 98, wherein the producer cell comprises at least one inserted selectable genetic marker complementing at least one mutation, preferably inserted selectable genetic marks complementing all said mutations.

100. The method according to claim 89, wherein the nucleotide sequence of at least one concatemer, preferably the nucleotide sequence from substantially all concatemers have been designed to minimise the level of repeat sequences in any one concatemer.

5

101. A method for evolving a cell producing at least one compound, said compound having two or more predetermined functionalities, said method comprising the steps of

10 a) providing a composition of cells, said composition of cells comprising cells with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition containing different heterologous expressible nucleotide sequences, said cells being denoted producer cells,

15

b) performing one screening of said population of cells for at least 2 parameters related to the functionalities, and determining a selection criterion for each parameter,

20 c) selecting cells meeting at least one predetermined selection criterion,

d) combining expressible nucleotide sequences of the selected cells with expressible nucleotide sequences from another composition of cells, thereby obtaining at least one new composition of cells, said new composition of cells comprising cells with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial chromosome in said cell, at least 2 cells of the composition containing different heterologous expressible nucleotide sequences,

30 e) optionally repeating steps b) to d) until at least one cell has acquired a compound having the at least two predetermined functionalities.

102. The method according to claim 101, wherein said another composition of cells comprises cells that contain expressible nucleotide sequences likely to confer at least one of the functionalities to the cells.

35

103. The method according to claim 101, wherein said another composition of cells was previously screened for a third functionality.
- 5 104. The method according to claim 101, wherein said another composition comprises heterologous expressible nucleotide sequences from expression states known to produce compounds with at least one of the desired functionalities.
- 10 105. The method according to claim 101, wherein said another composition comprises heterologous expressible nucleotide sequences that code for similar enzyme activities as heterologous expressible nucleotide sequences in the selected composition of cells.
- 15 106. The method according to claim 101, wherein said another composition of cells comprises cells capable of expressing at least one predetermined protein/enzyme or synthesising at least one predetermined compound or substance.
- 20 107. The method according to claim 101, wherein said another composition of cells is chosen at random.
108. The method according to claim 101, wherein said another composition is identical to the selected composition and expressible nucleotide sequences are mixed to obtain new combinations of the selected expressible nucleotide sequences.
- 25
109. The method according to any of the preceding claims 101-107, wherein the combination of expressible sequences is a combination of artificial chromosomes in the cells.
- 30
110. The method according to claim 109, wherein said combination of chromosomes is obtained by a sexual cross between cells.

111. The method according to any of the preceding claims 101 to 110, wherein substantially all heterologous expressible nucleotide sequences are located on one or more artificial chromosomes.
- 5 112. The method according to any of the preceding claims 101 to 111, wherein the combination of heterologous expressible sequences is conducted by isolating the heterologous expressible sequences from at least two different cells, combining the individual heterologous expressible sequences into novel combinations, and introducing the combined heterologous expressible
10 sequences into cells to obtain cells with at least 2 cells with different combinations.
113. The method according to any of the preceding claims 101 to 111, wherein the combination of heterologous expressible nucleotide sequences is
15 conducted by amplifying expression cassettes by PCR, mixing amplified expression constructs, combining the individual expressible nucleotide sequences into novel combinations and introducing the combined heterologous expressible nucleotide sequences into cells to obtain cells with at least 2 cells with different combinations.
20
114. The method according to any of the preceding claims 101-113, wherein said composition is a collection of sub-compositions.
115. The method according to claim 114, wherein a sub-composition is a
25 collection of individual cells having at least one phenotype in common.
116. The method according to any of the preceding claims 101-115, wherein the composition comprises at least 20 genetically different cells.
- 30 117. The method according to any of the preceding claims 101-116, wherein a composition of cells comprises at least 10^3 genetically different cells, more preferably at least 10^4 , more preferably at least 10^5 , more preferably at least 10^6 .

118. The method according to any of the preceding claims 101-117, wherein a composition of cells comprises at least 10^7 genetically different cells, such as at least 10^8 genetically different cells, for example at least 10^9 genetically different cells, for example at least 10^{10} , such as at least 10^{11} , for example at least 10^{12} , such as at least 10^{13} , for example at least 10^{14} , such as at least 10^{16} , for example at least 10^{18} , such as at least 10^{20} .
119. The method according to claim 114, wherein each sub-composition comprises at least 10 genetically different cells.
120. The method according to claim 114, wherein each sub-composition at least 10^3 genetically different cells, more preferably at least 10^4 , more preferably at least 10^5 , more preferably at least 10^6 .
121. The method according to claim 114, wherein each sub-composition comprises at least 10^7 genetically different cells, such as at least 10^8 genetically different cells, for example at least 10^9 genetically different cells.
122. The method according to any of the preceding claims 101-121, wherein the steps a) to c) are as defined by any of the claims 1-100.
123. A screening system comprising a producer cell and at least two reporter systems, wherein each of the reporter systems is directed to a parameter related to a functionality of one compound produced by the cell.
124. The screening system according to claim 123, comprising a producer cell encapsulated in a gel droplet together with the at least two reporter systems.
125. The screening system according to claim 123, comprising a producer cell in a liquid environment together with the at least two reporter systems.
126. The screening system according to claim 123, wherein the screening system is adapted for being used in a method as defined by any of the claims 1-100.

127. The screening system according to claim 123, wherein the screening system is adapted for being used in a method as defined by any of the claims 101-122.

5 128. A method for generation of lead compounds, said method comprising screening a composition of producer cells for at least two parameters related to at least two predetermined functionalities, said composition of cells comprising cells each with at least two heterologous expressible nucleotide sequences, at least one of said heterologous sequences being located on an artificial
10 chromosome in said cell, at least 2 cells of the composition contain different heterologous expressible nucleotide sequences.

129. The method according to claim 128, wherein the lead compounds are drug lead compounds and at least one parameter is related to absorption,
15 distribution, metabolism, excretion or toxicity and at least one further parameter is related to activity against a pharmacological target.

130. The method according to any of the preceding claims 128-129, wherein screening is as defined by any of the claims 1-100.

Desired profile: inhibition of NF-kB and Cox-2 but not Cox-1

- Initial screening rounds:
select cells that fit some of the criteria
- Later screening rounds:
select cells that fit all the criteria

INTERNATIONAL SEARCH REPORT

Internat Application No
PCT/DK 03/00044

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 C12N15/10 C12Q1/68

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 7 C12N C12Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, BIOSIS, WPI Data, PAJ

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	<p>WO 98 58085 A (KELLER MARTIN ;SHORT JAY M (US); DIVERSA CORP (US)) 23 December 1998 (1998-12-23) cited in the application the whole document in particular abstract; figures 14,15,18 page 12, line 22 -page 14, line 13 page 24, line 8 - line 21</p> <p style="text-align: center;">--- -/--</p>	1-130

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *G* document member of the same patent family

Date of the actual completion of the international search

19 May 2003

Date of mailing of the international search report

11/06/2003

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
NL - 2280 HV Rijswijk
Tel. (+31-70) 340-2040, Tx. 31 651 epo nl,
Fax: (+31-70) 340-3016

Authorized officer

Mossier, B
